

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

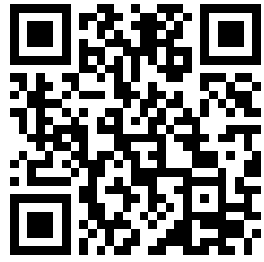
Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.

+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.

+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.



Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

MEDICAL SOCIETIES.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—Annual dinner, 1697

ÆSCULAPIAN SOCIETY.—Exhibition of cases and specimens; Hypodermic injection of cocaine; Notes on cases of traumatic fracture of the thigh; Fatal secondary hæmorrhage from the liver and perforation of the gall-bladder, 1390

ANDERSON'S COLLEGE MEDICO-CHIRURGICAL SOCIETY.—Fiftieth annual dinner, 1697

ASSOCIATION OF AMERICAN PHYSICIANS.—Chronic nephritis unassociated with albuminuria, 591

ASSOCIATION OF GERMAN NATURALISTS AND PHYSICIANS.—Facial neuralgia, 1340

ASSOCIATION OF REGISTERED MEDICAL WOMEN.—Intestinal obstruction complicated with malposition of the colon, 8—Meningitis; Aix-les-Bains, 1038—Carcinoma uteri, 1301

BEDFORD MEDICAL SOCIETY.—Fracture of the coronoid process of the ulna, 1242

BIRKENHEAD MEDICAL SOCIETY.—Annual meeting and election of office-bearers, 1080—Inaugural address, 1393—Operation for subluxation of the knee-joint, 1652

BOMBAY MEDICAL AND PHYSICAL SOCIETY.—Plague in Bombay, 105—Surgical symptoms in connexion with filaria sanguinis, 929

BOURNEMOUTH MEDICAL SOCIETY.—Annual meeting and election of office-bearers, 1225—Tubercle bacillus and x rays, 1314

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—The value of bacteriological research in the diagnosis of infectious disease, 1122—Midwifery; Club foot, 1324

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—President's address, 1122—Exhibition of cases and specimens, 1504

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—Election of officers; Climatic treatment of phthisis; Gouty liver and sulphur spas, 22—Presidential address; Chair of medical climatology and geography, 1226, 1251—Treatment of syphilis, 1699

BRITISH GYNÆCOLOGICAL SOCIETY.—Carcinoma of the cervix treated by curettage and chloride of zinc paste; Puerperal peritonitis treated with antistreptococcic serum; Exhibition of specimens, 22—Mechanism of inversion of the uterus; Escharotics in the treatment of uterine cervical cancer, 148—Exhibition of specimens; Dysmenorrhœa, 1048, 1322—Hæmorrhagic endometritis; Exhibition of specimens, 1650

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—Laryngeal growths; Exhibition of specimens, 337—Election of officers, 945—Exhibition of cases, 1362

BRITISH ORTHOPÆDIC SOCIETY.—Exhibition of cases, 1529

CLINICAL SOCIETY.—President's address; Loreta's operation for stricture of the pylorus; Cerebral sinus thrombosis; Impaction of tooth-plate in the œsophagus, 983—Congenital dislocation of both hips on to the pubes; Primary tuberculosis of the nares; Nævus of the frontal region, 1117—Calot's operation for the immediate reduction of angular deformity of the spine, 1203, 1319, 1455—Acute intestinal obstruction; Vesical calculus as a result of injury of the bladder during the operation for radical cure of hernia; Cases of intussusception, 1592

CORK MEDICAL AND SURGICAL ASSOCIATION.—Annual dinner, 1149

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—Exhibition of cases, 122, 1191, 1504

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—First meeting of the session, 1286—Glandular enlargements in the neck, 1326; serum reaction of enteric fever, 1593

EDINBURGH OBSTETRICAL SOCIETY.—Election of an honorary Fellow, 714—Valedictory address on the history of ovariotomy and the law of professional secrecy; Natural parturition; Election of officers, 1391

EDINBURGH ROYAL MEDICAL SOCIETY.—Election of office-bearers, 1220—Infantile scurvy, 1357

EPIDEMIOLOGICAL SOCIETY.—The annual dinner, 37—International sanitary conferences of the Victorian Era, 1266, 1516—Leprosy in China, 1694

FORFARSHIRE MEDICAL ASSOCIATION.—Vesical calculus and piperazin; Disinfection of rooms by spraying; Chyle in the pleura, pericardium and peritoneum; Exhibition of cases and specimens, 1018—Chronic stenosis of the large intestine, 1326—Bradycardia; Abdominal cases, 1596

FRENCH ACADEMY OF MEDICINE.—Aneurysm treated with gelatin, 58—Resection of the cervical sympathetic for goitre, 120, 332—Chloride of zinc in hernia, 171, 420—Serum treatment of plague, 225—Normal thromboses in the placenta, 287—Antitetanus serum as a preventive; Removal of the thyroid body in goitre; Adherent ulcer of the stomach, 332—The treatment of hernia, 420—The operative treatment of spinal curvature, 553—Holothyrus coccinella, 624—The etiology of cirrhosis in the intemperate, 748, 1083, 1289, 1486—Intestinal lavage in toxic conditions of the bowel, 748—Dangers in operations for exophthalmic goitre, 815—Filtered water for the army, 815—Gunshot wounds of the abdomen; Erratic eruption of wisdom teeth; Intestinal parasites in China, 887—Anti-leprous serum, 951, 1015—Dust in living-rooms, 1015—Treatment of tuberculosis by euphorbia resin, 1289—Bone-grafting, 1487—Phosphorus necrosis, 1627—The eunuch-like voice, 1627

FRENCH ASSOCIATION D'UROLOGIE.—Castration or vasotomy for enlarged prostate, 1258

FRENCH SOCIETY OF SURGERY.—The etiology of appendicitis, 1563

FRENCH THERAPEUTICAL SOCIETY.—Pathology and treatment of membranous colitis; Manufacture of the alkaloids, 1222

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—Election of secretary, 1626

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Election of office-bearers; Extra-uterine pregnancy; Exhibition of specimens, 1286

GLASGOW SOUTHERN MEDICAL SOCIETY.—Election of office-bearers, 1019—Exhibition of cases, 1459—Nasal obstruction and asthma due to turbinal hypertrophies, 1562

HARVEIAN SOCIETY.—The use of large doses of creosote in phthisis, 1119—A first series of fifty ovariotomies, 1177—The treatment of lateral curvature of the spine, 1250—Annual dinner, 1266—Hernia of the abdominal cicatrix and operations for its cure, 1379, 1456—Empyema of the antrum of Highmore, 1456—Syphilitic diseases of the eye, 1511, 1577, 1637

HUNTERIAN SOCIETY.—Headaches, 307—Some relationships of indigestion, 1030—Exhibition of cases, 1252, 1650—Medical hæmorrhage, 1312, 1322—Pruritus vulvæ, 1322—Chronic dry catarrh of the middle ear; Value of the microscopical examination of uterine curettings, 1534

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY.—First meeting of the session, 1226—Exhibition of cases, 1504, 1693

ISLE OF MAN MEDICAL SOCIETY.—Medical geography as an aid to clinical medicine, 237

KIDDERMINSTER MEDICAL SOCIETY.—Exhibition of cases, 1536

LEEDS AND WEST-RIDING MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases and specimens, 1121—Chronic intestinal obstruction, 1323

LIVERPOOL MEDICAL INSTITUTION.—Inaugural address and dinner, 814—A visit to Poland and Russia, 1079—Strangulation of the ileum by passage through a congenital mesenteric hole, 1111, 1120—Excision of the kidney for primary carcinoma; The typhoid serum reaction in doubtful cases of fever; Clinical and statistical evidence of the value of antitoxin in the treatment of diphtheria, 1120—The immediate correction of deformity in Pott's disease, 1252—Exhibition of specimens, 1324—Biennial dinner, 1356—An account of nine operations on the liver, 1457—Changes in the spinal cord, 1595—Chloro-

Digitized by Google

form in removal of tonsils; cleft palate and hare-lip operations; Pneumothorax; traumatic cyst of the iris, 1651

MANCHESTER CLINICAL SOCIETY.—Alteration of rules, 1285—The vis medicatrix naturæ in disease of the kidneys, 1518

MANCHESTER MEDICAL SOCIETY.—The appendices epiploicæ, 1325—Henoch's purpura, 1594

MANCHESTER PATHOLOGICAL SOCIETY.—Election of office-bearers, 1000—Exhibition of specimens, 1086, 1595—The means by which milk becomes pathogenic, 1325

MANCHESTER THERAPEUTICAL SOCIETY.—Toxic symptoms caused by phenacetine; Senecio Jacobæa, 1226—Thyroid medication; Orthoform, 1504

MEDICAL SOCIETY OF LONDON.—Red meat diet in gout, 11—Motor and sensory aphasia, 185—Some of the nervous disorders of the heart; John Arderne and his time, 873, 982, 1063—Cases in which an abdominal section has been performed a second time, 970—The localisation of rheumatism and chorea, 1116—Mitral stenosis; Cretinism; Inoperable tumours treated with injections of Coley's fluid; Multiple subcutaneous tumours, 1247—Treatment of pyo-pneumothorax; Mechano-therapy of moveable kidney, 1389—Cases of cysts of the pancreas treated by incision and drainage, 1591

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

BIRMINGHAM GENERAL HOSPITAL.—A case of acute general suppurative peritonitis treated by laparotomy (under the care of Mr. L. Gamgee), 916

BRISTOL GENERAL HOSPITAL.—A case of multiple aneurysm; necropsy; remarks (under the care of Dr. J. Lacy Firth), 19

BRITISH HOSPITAL, BUENOS AYRES.—Three cases of abscess of the liver (under the care of Dr. J. O'Conor), 858

BURTON-ON-TRENT INFIRMARY.—A case of Cæsarean section (under the care of Mr. P. B. Mason), 1317

BULAWAYO HOSPITAL.—A case of abscess of the liver; operation; recovery (under the care of Dr. F. Arnold), 1245

CANNING-TOWN MEDICAL MISSION HOSPITAL.—A case of ulcerative endocarditis treated with anti-streptococcic serum (under the care of Dr. Margaret Pearse), 92

DERBYSHIRE ROYAL INFIRMARY.—A case diagnosed as acute inflammation of the pancreas in which recovery took place (under the care of Dr. Milnes), 661

EDINBURGH ROYAL INFIRMARY.—A case of progressive pernicious anæmia of unusually rapid development, associated with marked jaundice, &c.; rapid recovery under large doses of arsenic (under the care of Dr. Byrom Bramwell), 197

FYZABAD SADR DISPENSARY.—A case of cirsoid aneurysm of the scalp; ligature and acupressure followed by immediate and complete excision; recovery (under the care of Surg.-Maj. J. J. Pratt), 21

GLASGOW VICTORIA INFIRMARY.—Case of extensive carcinoma of the stomach for which jejunostomy, as modified by Maydl, was successfully performed (under the care of Mr. A. Ernest Maylard), 1464

GLASGOW WESTERN INFIRMARY.—A case of excision of the cæcum for multiple fistulæ, with use of Murphy's button; recovery (under the care of Dr. J. C. Renton), 540

GOVERNMENT CIVIL HOSPITAL, HONG-KONG.—A case of delirium tremens; sudden hyperpyrexia; necropsy (under the care of Mr. J. Bell), 859—A case of abdominal hysterectomy for malignant disease (under the care of Dr. J. M. Atkinson), 1532

GREAT YARMOUTH GENERAL HOSPITAL.—A case of tetanus treated with tetanus antitoxin; death (under the care of Dr. H. Blake), 1114

GUY'S HOSPITAL.—A case of gonorrhœa with extensive suppuration; urinary and fæcal extravasation (under the care of Mr. C. Lucas), 197—A case of sarcoma of the upper jaw in a woman twenty years of age; excision; recovery (under the care of Mr. C. Lucas), 916

HALIFAX ROYAL INFIRMARY.—A case of polypus of the epiglottis; sub-hyoid pharyngotomy; necropsy (under the care of Dr. Priestley Leech), 390

HERTFORD BRITISH HOSPITAL, PARIS.—Recovery under digitalis in large doses in a case of apparently imminent death (under the care of Dr. Alan Herbert), 1114

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—Two cases of hydronephrosis (under the care of Mr. Edmund Owen), 1463

JAMSETJEE JEJEEBHOY HOSPITAL, BOMBAY.—A case of obstruction of the pylorus from spasm of the sphincter; Loreta's operation; recovery (under the care of Surg.-Lieut.-Col. W. K. Hatch), 1046

KENT AND CANTERBURY HOSPITAL.—A case of catheter fever; death in twenty hours; necropsy (under the care of Dr. Whitehead Reid), 1244

LEEDS GENERAL INFIRMARY.—A case of primary dysmenorrhœa with epilepsy cured by dilatation; remarks (under the care of Dr. J. Braithwaite), 255—A case of ligature of the external iliac artery for aneurysm by the transperitoneal method (under the care of Mr. W. H. Brown), 1047—A case of Aneurysm of the left popliteal artery treated by removal of the aneurysmal portion of the vessel (under the care of Mr. H. Littlewood, 1588

LIVERPOOL NORTHERN HOSPITAL.—A case of acute general suppurative peritonitis treated by laparotomy; recovery (under the care of Mr. Chauncy Puzey), 1385

LONDON TEMPERANCE HOSPITAL.—A case of Pirogoff's amputation (under the care of Dr. W. J. Collins), 601—A case of ruptured pyosalpinx closely simulating perforation of the appendix; necropsy (under the care of Dr. Soltau Fenwick), 1385

MELBOURNE HOSPITAL.—A case of rupture of the liver; operation; recovery (under the care of Dr. W. Moore), 742

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Case of large parotid tumour successfully removed from an old man (under the care of Mr. F. Paget), 20—A case of relapsing pneumonia (under the care of Dr. Thomas Oliver), 601—A case of hæmatosalpinx (under the care of Dr. Thomas Oliver), 1317—A successful case of pylorectomy (under the care of Dr. G. H. Hume), 1531

NORFOLK AND NORWICH HOSPITAL.—A case of hæmatomyelia; necropsy; remarks (under the care of Mr. C. Williams), 311

NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—A case of "chronic malignant endocarditis"; necropsy (under the care of Dr. G. D. Pidcock), 660

NORTH STAFFORDSHIRE INFIRMARY.—A case of rupture of the trachea; necropsy (under the care of Mr. J. Alcock), 793

ROYAL FREE HOSPITAL.—A case of congenital shortness of metacarpal and metatarsal bones (under the care of Mr. E. W. Roughton), 19—A case of dilatation of the stomach associated with peripheral neuritis (under the care of Dr. W. Carr), 721

ST. BARTHOLOMEW'S HOSPITAL.—A case of pyæmia and acute suppurative arthritis with complete recovery of the joints (under the care of Mr. Butlin and Mr. Lockwood), 91—A case of gumma of the isthmus of the thyroid gland; ulceration; œdema of the larynx; laryngo-tracheotomy; recovery (under the care of Mr. Bruce Clarke), 389—A case of strangulated partial enterocele of the cæcum without symptoms; fæcal fistula; resection of part of the cæcum; recovery (under the care of Mr. A. A. Bowlby), 793—A case of streptococcus pyæmia treated with anti-streptococcic serum (under the care of Mr. Butlin), 980

ST. GEORGE'S HOSPITAL.—A case of acute yellow atrophy of the liver in a girl twelve years old; necropsy (under the care of Dr. Cavafy), 145—A case of persistent hæmoptysis in phthisis relieved by venesection (under the care of Dr. W. Ewart), 539

ST. MARY'S HOSPITAL.—A case of typhoid fever without ulceration of the intestine (under the care of Dr. Cheadle), 254—Five cases of injury to the head (under the care of Mr. H. W. Page), 980—A case of aneurysm of the abdominal aorta, with symptoms of renal colic; necropsy (under the care of Dr. Cheadle), 1316

SALFORD ROYAL HOSPITAL.—Two cases of gangrenous strangulated hernia; resection of bowel; recovery in one case (under the care of Mr. Edmund T. Milner), 1531

SEAMEN'S HOSPITAL, GREENWICH.—A case of pneumonia followed by abscess of the lung, empyema, and death with hyperpyrexia; necropsy (under the care of Dr. J. Curnow), 1188

STANLEY HOSPITAL, LIVERPOOL.—A case of uræmic eclampsia in the seventh month of pregnancy; inhalations of oxygen; recovery (under the care of Dr. C. J. Macalister), 146—A case of herpes; gangrene; death (under the care of Mr. Douglas Crawford), 1114

UNIVERSITY COLLEGE HOSPITAL.—A case of diphtheritic conjunctivitis (under the care of Mr. Percy Flemming), 857—Two cases of interstitial hernia (under the care of Mr. A. E. Barker), 1244

WEST LONDON HOSPITAL.—A case of "antitoxin fever" (under the care of Dr. Seymour Taylor), 1650

WESTMINSTER HOSPITAL.—A case of ruptured hydro-encephalocele with extreme congenital hydrocephalus; excision (under the care of Mr. Walter Spencer), 1043

WORCESTER GENERAL INFIRMARY.—A case of inguinal hernia with bladder in the wall of the sac (under the care of Mr. T. Bates), 917

LIST OF ILLUSTRATIONS.

Drawing of Differential Air Calorimeter and Diagram of Rubner's Calorimeter, accompanying Croonian Lectures on the Means by which the Temperature of the Body is maintained in Health and Disease (Dr. W. Hale White), 2, 4

Views of Abdominal Contents illustrating case of Intestinal Obstruction complicated with Malposition, apparently congenital, of the Colon (Dr. Florence Nightingale Boyd), 9

Diagram of Apparatus for Draining the Bladder through a Suprapubic Opening, as described in paper on an Operation for the Amelioration of Incurable Incontinence of Urine (Dr. W. Alexander), 17

Reproduction of Roentgen Photograph of Hand showing Congenital Shortness of Metacarpal Bones (Mr. E. W. Roughton), 19

Portrait of a Man suffering from a Large Parotid Tumour which was successfully removed (Mr. F. Page), 20

An efficient Drainage Plug for Gastrostomy, Colotomy, Operations on the Gall-bladder, &c. (Mr. W. A. Lane), 27

Emergency Infusion Cannula (Dr. W. C. Hossack), 28

An Improved Pattern of "Giant" Lithotrite (Mr. D. F. Keegan), 28

View of Syracuse from the Sea-Front, illustrating THE LANCET Special Commission on Sicily as a Health Resort, 41

Portrait of Child who had undergone Amputation of both Lower Extremities on account of Dry Gangrene complicating ordinary Scarlet Fever (Mr. A. E. Pearson and Mr. H. Littlewood), 85

Temperature Chart of a case of Ulcerative Endocarditis treated with Anti-streptococcic Serum (Dr. Margaret Pearse), 93

Diagram of Rotating Notched Disc employed by Mr. Shelford Bidwell for obtaining the Visual Phenomena of the After Image, 99

Drawings of Globular Urates, Needle Urates, Articular Cartilage containing Urates, masses of Uric Acid Crystals, and a Uric Acid Calculus undergoing Solution, illustrating paper on the Pathogenesis of Gout (Dr. C. Mordhorst), 131, 132, 133, 134, 135

Instruments for the Treatment of Urethral Stricture (Acorn-headed Stem and Urethrotome) described in paper on Resilient Stricture of the Urethra (Mr. C. W. MacGillivray), 137

New Palpebral Forceps (Mr. H. Work Dodd), 150

Back view of a case of Ischio-rectal Hernia due to Dislocation of a Subperitoneal Fibroma (Mr. J. Lynn Thomas), 192

Portrait of Child suffering from Glioma, together with Microscope-fields showing Glioma Cells and the Cells of the Fœtal Retina (Dr. C. B. Taylor), 192, 193

Instruments described in paper on the Treatment of Lacrymal Obstruction by Styles (Mr. R. S. Miller), 194, 195

Facsimile of Letter written by Admiral Lord Nelson within ten weeks after the Amputation of his Right Arm, accompanying paper on Nelson as a Patient (Mr. Edmund Owen), 196

New Cycle Midwifery Bag (Mr. J. C. Clark), 203

New Tonsil Forceps (Dr. H. A. Smith), 203

New Apparatus for Administering Anæsthetics and other Volatile Vapours (Professor Hobday), 203, 204

Outline Map of the Registration Districts of the Isle of Man, illustrating paper on Medical Geography as an aid to Clinical Medicine (Mr. Alfred Haviland), 238

The "Facile Princeps" Bedstead, 259

Eight Portraits illustrating article on the Twelfth International Medical Congress at Moscow—the Czar, the Grand Duke Sergé Alexandrovitch, Professor N. V. Skliffosowski, Professor I. F. Klein, Professor A. J. Kojevnikof, Professor V. K. Roth, Professor Victor Vassilievitch Pashutin, and Professor N. F. Filatov, 274, 275, 276

Longitudinal Sagittal Section of the Cervical Spinal Cord, illustrating paper on a case of Traumatic Hæmatomyelia (Mr. C. Williams), 311

Portraits, Views in Moscow, and Drawings accompanying article on Medicine, Past and Present, in Russia—the Koul-Oba Vase and Diagram representing groups of Figures on it, Dr. Mark Ridley, two Views of the University of Moscow, three Views of the Moscow Clinique, Baron Dimsdale, M.D., Dr. John Rogerson, Reverse and Obverse of Medal with Head of Sir James Wylie, Bart., Nicolaus Pirogof, and Professor S. P. Botkin, 344, 345, 349, 351, 357, 358, 359, 363, 369, 373

Drawings showing Artificial Pupil after operation by the usual method and also after the method described in accompanying paper (Dr. C. B. Taylor), 388

New Portable Eye Instrument Steriliser, 393

Drawings illustrating paper on Decalcified Ivory Discs for End-to-end and Lateral Anastomosis of the Intestine (Dr. R. Martin Gil), 522, 523

Clamp for Ileum and Colon referred to in paper on Excision of the Cæcum for Multiple Fistulæ, with use of Murphy's Button (Dr. J. Crawford Renton), 540

Polymelian Canine Monstrosity, 544

Sketch showing Relative Lengths of Stumps after Syme's and Pirogof's Amputations, illustrating a paper on a case of Pirogof's Amputation (Dr. W. J. Collins), 601

Temperature Chart of a case of Relapsing Pneumonia (Dr. T. Oliver), 602

Drawing of Cataracta Complicata Accreta, accompanying paper on a case of Apparently Incurable Blindness in which Sight was restored (Dr. C. B. Taylor), 653

Diagram of Bladder accompanying description of a case of Double Vasectomy (Dr. W. F. Colclough), 659

Lion Forceps for use in Screwing, Wiring, and other Operations on Bone (Dr. E. A. Peters), 665

An improved Pince-nez, 666

Diagrams of the Trunk of the Body, showing the Appearances described in paper on the Roentgen rays in Medical Diagnosis (Dr. H. C. Thomson), 710, 711

Vaginal Forceps and Director, referred to in description of a case of Pan-Hysterectomy (Mr. M. U. O'Sullivan), 714, 715

New Hernia Corset (Dr. F. W. A. Stott), 728

An Improved Œsophageal Probang (Mr. C. J. Mayhew), 728

Drawings illustrating paper on Congenital Absence or Delayed Development of the Patella (Mr. E. M. Little), 783

Diagram showing the Laryngoscopic Appearance presented by a Piece of Bone lodged in the Trachea for Nine Years, together with Diagram showing the actual size of the Bone (Dr. J. Le M. Bunch and Mr. R. Lake), 785

New Stricture Dilator (Mr. T. Jackson), 798

Automatic Wound Retractors (Mr. R. H. Lucy), 798

New Anæsthetic Mask (Mr. W. E. Burton), 798

The Pneumatic Medicator and Injector (Mr. D. Johnston), 799

Nine Portraits illustrating paper on Sporadic Cretinism (Dr. A. G. Paterson), 850, 851, 852, 853

Two Portraits illustrating paper on the Tendency to Bending of the Bones in Cretins under Thyroid Treatment (Dr. T. Telford-Smith), 853, 854

Two Portraits illustrating paper on a case of Cretinism successfully treated with Thyroidin (Mr. C. M. Anderson), 856

Axis-Traction Forceps (Dr. F. M. Purchas), 863

The Esmond Saddle, 863

A New Surgical Lamp (Dr. H. H. B. Hickman), 864

A Wrist-Easel (Dr. D. Grant), 922

Thermograph Chart showing a Continuous Record of the Temperature for about Four Successive Days, accompanying paper on Helouan, its Climate, Waters, and Recent Improvements (Dr. W. P. May), 934

Map accompanying Report on the Epidemic of Typhoid Fever at Maidstone (THE LANCET Special Commissioner), 919

Ten Figures of Patients accompanying Lecture on some Typical Forms of Curvature of the Spine (Mr. Noble Smith), 962, 963, 964, 965

Two Diagrams illustrating paper on the Removal of a Bullet from the Thigh after Three Years by the Aid of X Rays (Dr. W. J. Collins), 977

New Aural and Throat Mirror (Mr. T. A. Goodchild), 989

A Moving Bed, 989

The "Christy" Anatomical Bicycle Saddle, 1053

Maps, Plans, &c., illustrating THE LANCET Special Commission on the Metropolitan Water-supply:—New River Company—Area supplied, Course of the New River, Survey of the New River from the Intake (River Lee) to Broxbourne, Survey of the New River from Broxbourne to Forty-hill, Survey of the New River from Hoe-lane Bridge to Hornsey Basin, Survey of the New River from Hornsey Reservoir to the New River Head, Hornsey and Campsbourne Stations, Stoke Newington Station, New River Head, Clerkenwell, The Hampstead and Highgate Ponds, 1069, 1205, 1207, 1269, 1271, 1405, 1473, 1611

LIST OF ILLUSTRATIONS—(*Continued*).

Four Drawings illustrating paper on Some Intestinal Experiments: a Rapid Method of Enterectomy (Mr. H. M. Jordan), 1099, 1104, 1105

Drawings accompanying paper on a Method of Uniting the Divided Intestine (Mr. G. L. Cheatle), 1113

Diamond Jubilee Portable Hospital Telephone, 1126

Diagrams of Thorax and Abdomen accompanying paper on a case of Anteverted Wandering Liver (Dr. R. Crawfurd), 1182, 1183

Drawings showing Tracheotomy Tubes, and the manner of using them, accompanying paper on the Administration of Anæsthetics through a Tracheal Wound (Professor T. Annandale), 1185

Temperature Chart of a case of Pneumonia followed by Abscess of the Lung, Empyema, and Death with Hyperpyrexia (Dr. J. Curnow), 1189

A Modified Pistonless Hypodermic Syringe (Surg.-Capt. J. W. Cockerill), 1194

Four Diagrams of the Stomach illustrating paper on a case of Pyloric Stenosis treated first by Loreta's Operation and afterwards by Posterior Gastro-Enterostomy (Mr. J. W. Taylor), 1235, 1238

Eight Figures of Antra, accompanying paper on the Surgical Anatomy of the Tympanic Antrum (Mr. R. Lake), 1242

A Surgical Bag (Mr. N. H. Forbes), 1256

Reversible Catheter and Bougie in one, 1256

A New Needle Holder (Dr. W. J. Branch), 1256

Drawing of a Disinfector described in paper on the Disinfection of Clothes by Heat (Mr. A. F. Messiter), 1306

A Mouth-Opener, 1331

Views of Houses referred to in Report on the Epidemic of Typhoid Fever at Lynn (THE LANCET Special Commissioner), 1354

Diagram showing the Distribution of Milk by Milkmen, referred to in paper on the Outbreak of Enteric Fever at Clifton (Dr. D. S. Davies), 1440

Diagram of Maydl's Operation, accompanying paper on a case of Extensive Carcinoma of the Stomach for which Jejunostomy, as modified by Maydl, was successfully performed (Mr. A. Ernest Maylard), 1454

A New Vaginal Tube (Mr. Haydn Brown), 1463

A Piano for Invalids, 1463

Portraits of Patients, Microscope Fields, and Section of the Eye, accompanying Harveian Lectures on Syphilitic Diseases of the Eye and its Appendages (Mr. H. E. Juler), 1513, 1514, 1515, 1516

Diagrams of Arm and Hand, illustrating paper on Paralysis of Muscles of the Upper Extremity of Peripheral Origin (Dr. R. T. Williamson), 1523, 1524

Diagrammatic Representations of Amœbæ accompanying paper on Tropical Abscess of the Liver (Dr. C. W. Windsor), 1528

New Portable Cautery, 1540

Diagram accompanying Description of a case of Aneurysm of the Left Popliteal Artery treated by Removal of the Aneurysmal Portion of the Vessel (Mr. H. Littlewood), 1589

Lupus Scrapers (Dr. G. G. S. Taylor), 1600

A New Cycle Saddle (Mr. J. MacMunn), 1635

Syringe described in paper on the Guaiacol Treatment of Laryngeal Tuberculosis especially by Submucous Injections (Dr. J. Donelan), 1649

END OF THE SECOND VOLUME FOR 1897.

The Croonian Lectures

ON

THE MEANS BY WHICH THE TEMPERATURE OF THE BODY IS MAINTAINED IN HEALTH AND DISEASE.

Delivered before the Royal College of Physicians of London, on June 15th, 17th, 24th, and 29th,

BY W. HALE WHITE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT, GUY'S HOSPITAL.

LECTURE III.[1]

Delivered on June 24th.

MR. PRESIDENT AND GENTLEMEN,—We now pass on to the second method which has been used in the endeavour to find out whether or not in fever the production of heat is increased—namely, calorimetry. The difficulty of the subject is very great, for although many experimenters have worked at it, if any reliable results have been published they are few, and I can well understand this, for I have been working at calorimetry for the last six years and have not yet satisfied myself that a trustworthy instrument has been made.

The calorimeter, which has hitherto been most frequently employed for measuring the heat given off by animals, is the well-known water calorimeter. Such an instrument was described by Crawford in 1788; and after reading the account of his experiments I doubt whether any of his successors have taken more elaborate precautions to ensure the greatest attainable accuracy. Other experimenters who have used water calorimeters are Dulong, Despretz, Senator, Wood, Desplats, Evans, Hare, Ott, Carter, Reichert, and Kemp. One of the most recent patterns of water calorimeter is that used by Reichert. It consists of two concentric boxes of sheet metal, which are fastened together so that there is a space of about one and a half inches between them filled with water. In the inner box the animal is placed, there being a suitable opening through both boxes for this purpose; the opening has an air-tight door. The inner box has leading into it two tubes—one for the entrance of air and the other for its exit. The outer box has a hole in it, through which passes a stirrer to stir the water between the two metal boxes, and another in which is fixed a thermometer to take the temperature of the water. The whole apparatus is surrounded by a thick packing of wool, feathers, or some other non-conductor, so that it is protected as far as possible from the effects of variations in the external temperature. The instrument is standardised before it is used for experiments on animals. This is done by burning in it enough of either hydrogen or alcohol to raise the temperature of the water 1°. It is known how many calories of heat are set free in the combustion of this quantity of hydrogen or alcohol, and therefore it is known that this number of calories is always given off to the instrument when the temperature of the water in it rises 1°. The temperature of the air entering and that of the air leaving the calorimeter is taken, and so any heat given off by the animal and expended in warming the air is estimated. Lastly, the moisture given off by the animal is determined, so that the heat expended in volatilising its aqueous vapour can easily be calculated. All water calorimeters are unreliable, chiefly because, firstly, as I have often found, even with the most careful mixing, it is impossible to get a large mass of water to a uniform temperature, and a slight error as to temperature means an enormous error in the result of the experiment. Secondly, water calorimeters act very slowly. For instance, in some of Senator's experiments at the end of an hour the temperature of the water had only risen 0·2° C., and after this the further rise was trifling. Many observers have not used water calorimeters. In 1780 Lavoisier and Laplace used an ice calorimeter, and Dr. Marcet showed one not long ago at the Physiological Society, but I cannot criticise it as he has not yet published an account of it.

In 1849 Scharling used a form of air calorimeter. Vogel and Hirn each employed instruments very like Scharling's. Rosenthal described an air calorimeter in 1878 and Richet published an account of an air calorimeter in 1885. This was employed by Langlois in 1887, and Mosso used a very similar instrument in 1890. Sapalski and Klebs also used an air calorimeter. The following objections can be urged against all these calorimeters: 1. The calorimeters which have been previously standardised are faulty, for the method employed to standardise is open to considerable sources of error. Thus Richet in standardising his got figures varying from 66 to 91 from which to strike an average, and Langlois obtained figures varying from 59 to 74; and I think, as I shall be able to show, that even where the figures are apparently more satisfactory they are not really of value if the instrument is to be used for animals. 2. Many conditions may not be the same during the standardising as during subsequent experiments. 3. All non-differential calorimeters are open to serious sources of error from the varying influence of the external air in abstracting heat from the instrument. Some experimenters have tried to allow for these and other errors (e.g., that due to variations of barometric pressure), but the correction is a very large percentage of the whole amount of heat produced. 4. In many calorimeters the ventilation is quite inadequate. 5. In some, as Richet's, if for any period during an experiment the production of heat decreases, this decrease is not measured by the instrument. In 1886 D'Arsonval gave an account of several calorimeters, including his differential air calorimeter, which presents evident advantages over those described up to this date. My own apparatus embodies D'Arsonval's principle, but chiefly differs from his differential instrument in that there is a source of heat in both chambers of the calorimeter. Since the publication of this paper by D'Arsonval, and since I began to work at calorimetry, other calorimeters, for the most part modifications of D'Arsonval's differential instrument, have been described by Rosenthal, Ansiaux, and Rubner and his pupils. Calorimeters such as those described by Liebermeister and Leyden, in which a part only of the body is inserted, are obviously unreliable, and so are the attempts made by Liebermeister, Kernig, and Hattwig to estimate the amount of heat produced by a man by immersing him in a water bath.

As differential air calorimeters have been most used, and have appeared to most observers to hold out the greatest promise of utility, I will describe in detail the one I have made. In making it I have derived much help from my friends, Dr. Haldane, Dr. Washbourn, and Mr. F. G. Hopkins. It consists of several parts (see Fig. 1).

The copper chambers.—These are two precisely similar cylindrical chambers made of thin sheet-copper and provided with convex roofs. The inside height of each is 18 in., and the inside diameter is the same. Each chamber has two walls (see diagram—A, A′ and a, a′), between which is an air space 1½ in. across and closed at the bottom by copper. Each chamber is by means of flanges turned out from its outer wall, A, a, firmly screwed on to a strong wooden table which stands on four wooden legs that are fixed to the floor of the laboratory. These legs are about 5 ft. high, so that it is easy with a little stooping to pass under them and open and shut the floor of the chambers. The floor of each chamber is a thick wooden disc (B, b) covered on its upper surface with copper. It is made of several layers of hard, well-seasoned wood, so arranged that it does not warp under variations of temperature and moisture. These two floors are similar in all respects. Each disc has on its upper surface and near its circumference a deep trough (C, c) cut in it all round. The inner wall A′ a′ of the copper chambers is prolonged down into the trough. The trough C, c, in each disc is filled with resin ointment, in which, when the disc is pushed up as far as it will go, the prolongation downwards of the inner wall of the copper chamber is embedded, the chamber being thus closed air-tight. Resin ointment was chosen after many trials of various substances as being the best for rendering the chamber air-tight. Many varieties of screws were tried for keeping the discs in position, but we found that if a deep trough with plenty of resin ointment is used the chambers would keep shut absolutely air-tight for an indefinite time if the discs were kept in place against the wooden casing of the chambers by a simple button. It is very necessary that the parts of the instrument should be so arranged that the bottom of the trough does not, when the disc is pushed home, touch the prolongation of the copper

[1] Lectures I. and II. were published in THE LANCET of June 19th and 26th, 1897, respectively.

into the trough, and that the disc itself presses at the wooden table, and not against the copper air-tight space, for as the copper of which this is made is thin any pressure on it is liable to make the air-tight joints of the air-space between the outer and inner copper walls of each chamber give, and if they are not absolutely air-tight the instrument is quite useless. Leading off from each air-space is an indiarubber tube, G, g. The two rubber tubes are connected with the two limbs of a manometer H.

The calorimeter is used in the following way. In one copper chamber the animal, the heat production of which we require to know, is placed. In the other hydrogen is burnt, both chambers being shut. The heat given off from the animal warms its chamber, and thus increases the pressure of the air in the air-space between the two copper walls of its chamber. This would lead to movement of the fluid in the manometer but that the heat given off by burning the hydrogen increases at the same time the pressure in the space between the walls of the other chamber. This latter increase of pressure tends to make the fluid move in the other direction. If the fluid in the manometer is stationary the amount of heat given off by the animal is, other things being equal, equal to that produced by the burning of the hydrogen. During an experiment the manometer is kept stationary by turning up or down the hydrogen flame. The amount of hydrogen burnt is estimated, and knowing the heat of combustion of hydrogen we can calculate the calories produced by the quantity used in the experiment, which equal those given off by the animal.

The casing.—The knowledge that fluctuations in the temperature and barometric pressure are a most important source of error in many air calorimeters led to our adopting the compensating principle of D'Arsonval, for it is clear that variations of temperature and barometric pressure in the air of the laboratory would affect both air spaces equally and, therefore, not move the fluid in the manometer. We found, however, that temporary draughts, &c., were apt to act somewhat unequally on the two chambers, and thus cause a certain amount of error, which might in extreme cases amount to as much as 0·5 calories per hour. After very many trials we discovered that this difficulty could be obviated by covering the chambers with three layers of felt each an inch thick. When this was done the level of the fluid in the manometer remained practically stationary unless some source of heat were introduced into one of the chambers. The felt is in the plate marked I, i, and is of the kind used for refrigerators. It is all covered in with the wood casing D, d. There is a small window in the floor of each chamber. It is closed air-tight by a piece of glass, J, j. The object of these windows is that the experimenters may see that the hydrogen flame is burning properly and that the animal is comfortable. During an experiment when the window is not in use it is covered with a thick pad of felt, F, f. We have sometimes used a variety of slag wool instead of felt—it is quite as efficient a non-conductor.

The manometer.—After many trials of different fluids and slopes of tubes we found the best manometer to be one (H in the diagram) in which the limbs are sloped at an angle of 45° with the horizon. The bore of the tube is one tenth of an inch in diameter. It is filled with oil of erigeron, as the specific gravity of that is very low and it moves readily. Behind one limb of the manometer is a ruled scale. The lines are one-thirtieth of an inch apart and each is numbered. The scale is so placed that the lines on it are parallel with the upper surface of the fluid in the manometer. At the beginning of an experiment a note is made of the line which corresponds to the upper level of the fluid, and by turning the hydrogen up or down the fluid is kept on this line during the whole experiment. The openings 2, 3, which are kept clamped, on the manometer tube are useful; for if at any time the fluid in one limb has from any cause got much higher than that in the other, opening the clamps immediately brings the fluid in the two limbs to the same level.

FIG. 1

The hydrogen.—The hydrogen is produced in a Kipp's apparatus, K, and is dried in the bottle L. It will be noticed that there is a hydrogen burner (M, m) in each copper chamber. A great advantage of this is that a control experiment can be done at any time, for if both copper chambers are shut air-tight, and hydrogen is burnt in each, one or other of the two flames being kept at such a height that the fluid in the manometer remains stationary, and it is then found that in the same time the same amount of hydrogen has been burnt in each chamber, it is evident that the instrument is not leaking. Some examples of this mode of control will be given immediately. Another reason for having a hydrogen burner in each copper chamber is that it is important for the fittings of the two chambers to be

Digitized by Google

similar in all respects, so that those of one may not absorb more heat than those of the other. Therefore, also, there is in the hydrogen chamber a wire cage exactly similar to that used for the animal in the other chamber. The cages have a floor to catch the urine, and feet to raise them from the floor of the chamber and so prevent loss of heat by direct conduction from the animal to the floor of the chamber. The indiarubber tubes which conduct the hydrogen to the burners each pass under a screw clamp N, n, by means of which the size of the hydrogen flame can be very accurately adjusted. The amount of hydrogen burnt is estimated by determining the amount of water produced. This is effected by passing a current of dry air into the calorimeter and estimating the moisture present in the outgoing air. The air entering the chambers is dried by means of Woulff's bottles (O, o), charged with pumice soaked in sulphuric acid. The air leaving the chambers is dried by being passed through the tubes P, p, which are filled with pumice soaked in sulphuric acid. Before the amount of moisture produced by burning the hydrogen in its chamber can be estimated the air in the chamber must be perfectly dry. To ensure this the chamber is shut up air-tight, the hydrogen not being lit, and then air which has been passed through a pumice and sulphuric acid bottle (O, o) is drawn through the chamber until a tube containing pumice and sulphuric acid placed in the outgoing air-current no longer increases in weight. Six experiments of this nature showed that in order to completely empty all the moist air out of the chamber, and to replace it by dry air, 300 litres of dry air are required to be passed through. The following are the results of one of these experiments. The gains in weight of the pumice and sulphuric acid in the outgoing air-current after successive portions of dry air had been passed into the chamber are given.

Gain in weight after 92 litres of dry air were passed through	0·52 grms.
Further gain after 107 additional litres of dry air were passed through	0·17 ,,
,, ,, 90 ,, ,, ...	0·05 ,,
,, ,, 87 ,, ,, ...	0·00 ,,
,, ,, 90 ,, ,, ...	0·00 ,,

Thus when 92 + 107 + 90 litres had been drawn through the air in the chamber was perfectly dry.

It is of great importance that the inner walls and floor of the chamber should present no hygroscopic surface. For this reason the floor is covered with copper. The employment of a painted surface gave endless trouble in the case of the first calorimeter in which the hydrogen method was employed.

Having dried the closed chamber the next thing is to light the hydrogen in it. This is effected by means of an electric spark. The wires Q, Q, proceeding from, and returning to, an induction coil R, connected with an accumulator S, are so arranged that a spark can be made to pass across the orifice of each hydrogen burner. The air in the chamber being dry a carefully weighed sulphuric acid and pumice tube is placed in the path of the outgoing current of air at P or p, as the case may be, according to which hydrogen burner is being used. The hydrogen is turned on; by passing the spark it is lit; and the aspiration through the chamber which had been stopped to put in the newly weighed bottle is started. The moisture is absorbed by the tube at P or p, as the case may be. In an experiment with an animal, at the time that the hydrogen is lit, the animal in its cage is put in the other copper chamber, which is then shut up, and air is drawn through it to provide for the creature's respiration. In order to make the conditions similar air is drawn through the two chambers at an equal rate, which must be sufficiently rapid to prevent condensation of moisture. During an experiment the hydrogen is kept by means of the screw clamp N or n at such a height that the fluid in the manometer remains stationary. When the experiment has lasted as long as is desired the hydrogen is turned out and the animal is taken out of its chamber. But as the air in the hydrogen chamber now contains moisture, and as we have already shown that to get rid of all the moisture in the chamber 300 litres of previously dried air must be drawn through it, this is done after the hydrogen is turned out. Then the increase in the weight of the tube at P or p will give the amount of moisture produced by the burning hydrogen. Suppose, for example, this were 4 grammes, then $\frac{1}{9}$ grammes = the weight of hydrogen burnt; and as the combustion of 1 gramme of hydrogen produces 34·2 kilogramme calories, $\frac{4}{9} \times 34{\cdot}2$ equals the number of calories produced by the combustion of hydrogen in this experiment. This heat, however, is not all given up to the calorimeter, since the moisture produced is not allowed to condense inside the chamber. The heat of condensation of this moisture is $9 \times 0{\cdot}59 = 5{\cdot}3$ calories for each gramme of hydrogen. Hence the heat given up to the calorimeter is $34{\cdot}2 - 5{\cdot}3 = 28{\cdot}9$ calories per gramme of hydrogen burnt, and this, in the instance we are supposing, multiplied by $\frac{4}{9}$ equals the heat given off by the animal. A calorie is taken to be the amount of heat necessary to raise one kilogramme of water through one degree Centigrade.

For turning out and lighting the hydrogen we found it convenient to have a spring clamp, T, t, on the hydrogen tubes, for then the hydrogen could be lit or turned out instantly; the screw clamp, N, n, is only used for adjusting the flame. It is absolutely necessary to show that the chamber and all the connexions are air-tight after the floor is pushed up at the beginning of an experiment. This is done by closing the inlet tubes to the bottles, O, o, and the hydrogen tubes, and then drawing a little air out of the apparatus and thus producing a negative pressure within, and then ascertaining—by means of the meter or a water manometer if the aspirating vat is used—whether this negative pressure is maintained. It will be noticed that the tube by which air enters the copper chamber is carried up to within an inch of the roof, while the orifice of the outlet tube is nearly flush with the floor. The object of this is to distribute the heat from the flame, and secure that by reflection from the roof the dry air entering the chamber shall be broken up as thoroughly as possible and so mixed with the moisture produced by the combustion of the hydrogen. A point we investigated was how much of the heat given off either by the burning hydrogen or by the animal was lost to the calorimeter, because it warmed the air drawn through the chambers. To determine this accurate thermometers were placed in the ingoing and outgoing currents of air, close to the copper chamber, by being inserted in an air-tight opening in the indiarubber tubes. It was found that after the animal had been in place, or the hydrogen had been burning an hour, the temperature of the outgoing air was never more than 0·4° C. higher than that of the ingoing. Now, usually 300 litres—that is to say, 400 grammes—of air were drawn through in an hour. The specific heat of air is 0·23; therefore, to warm 400 grammes of air through 0·4° C. would take $0{\cdot}4 \times 0{\cdot}23 \times 0{\cdot}4 = 0{\cdot}037$ calories. But as a large rabbit gives off about nine calories an hour the heat given off by the animal or hydrogen flame, and not felt by the calorimeter because it is expended in warming the air, is only 0·4 per cent. of the total amount produced by the animal. As this amount is so small and is the same on the two sides of the calorimeter it may safely be neglected.

The instrument I have described to you is not quite the same as that which Dr. Haldane, Dr. Washbourn, and I described in the *Journal of Physiology*, but the principle is the same. The calorimeter of which I have now given an account is one that I made with Mr. Hopkins. It possesses several minor advantages over the instrument described in the *Journal of Physiology*. Its wooden casing is better than a casing of American cloth. The absence of pressure on the copper by the floor is very important, and it saves much trouble to dispense with the old arrangement for screwing the floor into position. It is much easier to ensure an air-tight space by having the window in the floor rather than in the walls of the air-tight space, and it is a great advantage to have the chambers so high from the ground that it is easy to pass under them. In the old instrument both chambers were fixed to one table, which made the whole very cumbersome and unwieldy, but as in the present instrument the manometer board is only on hooks the chambers with their casings are easily separated, the pumice tubes, the Kipp's apparatus, the induction coil, and the accumulator can easily be removed from the flaps on which they stand and the flaps let down. The long legs take off, and so the instrument can be easily moved. Lastly, we used a tube of pumice and sulphuric acid instead of a Woulff's bottle in the outgoing current, as that is easier to weigh.

Now I will bring forward some experiments to show that the instrument is correct in principle. In seven experiments both chambers were shut and shown to be air-tight. It was not necessary to empty them of the moist air they contained, for as both had been left open to the outside air before being shut the air in each contained the same amount of moisture. A sulphuric acid and pumice bottle was put in the path of the entering air and a weighed sulphuric acid and pumice

Digitized by Google

tube was placed in the path of the air leaving each chamber. The hydrogen was simultaneously lit in both chambers, and the flame was kept in each at such a height that the fluid in the manometer was stationary. Aspiration at an equal rate through each chamber was carried on, and at the end of a given time, usually about an hour, both hydrogen flames were simultaneously turned out. Aspiration was then continued through both the chambers till 300 litres of air had been drawn through each after the hydrogen was turned out. By this means the equal amounts of moisture originally in each chamber and all the water produced by the burning hydrogen in each were absorbed. But as the fluid in the manometer had been kept stationary, or as nearly so as possible, it is clear that if the instrument is efficient equal amounts of hydrogen should have been burnt—that is to say, equal amounts of water should have been produced. Therefore, if the increase of weight of the sulphuric acid and pumice bottles attached to the exit tubes of each chamber was identical the instrument was working satisfactorily. The following table shows the results of these seven experiments (see Table XVIII.).

TABLE XVIII.

Grammes of water produced by hydrogen burning in west chamber.	Grammes of water produced by hydrogen burning in east chamber.	Error per cent.	No. of experiment.
3·98	3·83	3·7	1
4·4	4·32	1·8	2
3·1	3·15	1·5	3
2·04	2·01	1·9	4
1·52	1·52	—	5
3·27	3·37	2·9	6
3·0	3·06	1·9	7

West in excess three times—viz., 3·7, 1·8, and 1·9 per cent.
East in excess three times—viz., 1·5, 2·9, and 1·9 per cent.
West and east equal once.
Average error that the west is in excess 0·17 per cent.

It will be seen that on no occasion was the error greater than 3·7 per cent., and in five out of the seven it was under 2 per cent. The great advantage, as I have already insisted, of these controls in which hydrogen is burnt in both chambers is that as each chamber is fitted with a hydrogen burner a control can be done at any time in the course of a series of animal experiments. As far as I know, no large number of observations on animals have been carried out with such a calorimeter as I have described. I have only done, with the help of some friends, a few on rabbits and guinea-pigs. While the animal is being weighed and its temperature being taken the chamber in which the hydrogen is going to be burnt should be shut up air-tight, and then 300 litres of air, which has previously passed through a pumice and sulphuric acid bottle, should be drawn through it. When this is done the air in it will contain no moisture. A weighed sulphuric acid and pumice tube is then put in the outgoing current of air from the hydrogen chamber. The cage for the animal is then taken out of its chamber, the animal is put in it, and the cage is replaced. The chamber is then shut up, the hydrogen in the other chamber is lit simultaneously, and the flame is kept at such a height that the level of the fluid in the manometer is stationary. An equal quantity of air is drawn through each chamber, care being taken that enough is drawn through to prevent a deposit of moisture in the chamber. At any given moment the animal may be taken out, but at the same moment the hydrogen must be turned out, the aspiration is continued through the hydrogen chamber for 300 litres, so that all the moisture produced by burning the hydrogen is collected in the exit sulphuric acid and pumice bottle. The latter is then weighed, and from the increase of weight we can easily calculate the number of calories given off by the burning hydrogen to the calorimeter, which must, as the manometer has been kept steady, equal the number of calories given off by the animal to the calorimeter. The following are the details of an actual experiment:—

	Grms.
Weight of sulphuric acid and pumice tube at exit of hydrogen chamber before experiment	3608·34
Weight of sulphuric acid and pumice tube at exit of hydrogen chamber after experiment	3607·92
Water produced by hydrogen flame =	1·58

$$\text{Hydrogen burnt} = \frac{1{\cdot}58}{9} = 0{\cdot}176 \text{ grammes.}$$

Calories produced in the chamber = 28·9 × 0·176 = 5·08 grammes.

The time the hydrogen was burning—that is to say, the time the animal was in its chamber of the calorimeter—was exactly one hour, so that the creature gave up to the calorimeter 5·08 calories per hour. The following are the results of four experiments made upon different days upon the same animal, a healthy brown male rabbit weighing 3080 grammes. The rectal temperature was always taken before and after the experiment (see Table XIX.).

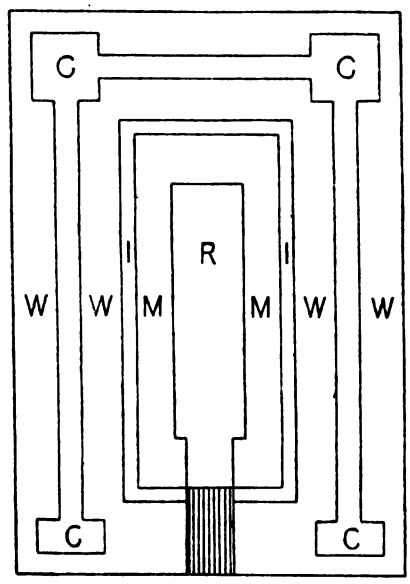

TABLE XIX.

Calories given off per hour by the rabbit to the calorimeter.	Number of experiment.
7·37	2
6·89	4
6·64	1
5·08	3

Now these figures do not represent all the heat given off by the animal. I have already shown that the heat expended in warming the air drawn through the apparatus may be neglected, but that which is employed in volatilising the aqueous vapour given off from the animal is not included. The quantity of this aqueous vapour is determined by means of a pumice and sulphuric acid tube in the path of the air coming from the exit of animal chamber. The heat required to evaporate a gramme of water at the temperature of the rabbit is a known constant (0·57 calorie), so that the heat expended by the animal in volatilising aqueous vapour can easily be obtained by multiplying 0·57 by the number of grammes of moisture given off by the animal. Thus when two guinea-pigs were in the calorimeter they gave off in an hour 1·74 grammes of moisture and $1{\cdot}74 \times 0{\cdot}57 = 0{\cdot}99$, so that they gave off 0·99 calories by evaporation, which turned out to be nearly a fourth of what they gave off by radiation and conduction.

Rubner and Nebelthau have worked with very similar instruments to that which I have described. I show you a diagram of a section of Rubner's calorimeter (see Fig. 2).

FIG. 2.

It consists of a copper chamber R, in which the animal is placed; the chamber is closed by a non-conducting air-tight door. The copper chamber R is surrounded by an air space M, M, just as the copper chamber in the calorimeter I first described is surrounded by an air space; the air in this space, M, M, is warmed by the animal, and as it expands it moves the dial of a registering apparatus, with which M, M, is connected by a tube. (This is not shown in the diagram.) I, I, is an air space closed on all sides by copper. The object of it is to surround the calorimeter with a good non-conductor, such as air. The whole is surrounded by a vessel containing a quantity of water, W, W, W. This also is

Digitized by Google

to prevent the variations of external temperature from influencing the calorimeter. This mass of water is automatically kept at a constant temperature, for there is a gas flame under it, and if it gets too warm more cold water automatically flows in from a tap and replaces some warm water which automatically flows away. I need not bother you with the details of this arrangement. The registering apparatus is under the influence of variations in barometric pressure, and therefore there is a very irregularly shaped copper chamber, C, C, C, in the water W, W, W. This copper chamber is connected with a separate registering apparatus of its own and shows variations in the barometric pressure, and these are allowed for when calculating the heat given off by the animal by observing the registering apparatus connected with the air space, M, M. Of course, the animal chamber is ventilated. The apparatus is standardised by placing a spirally coiled tube in the animal chamber, letting warm water flow through the coil for a given time, and at the same time observing the movement of the registering dial connected with the air space around the animal chamber. The temperature of the water is taken before it enters and after it leaves the coil, and from these data it is easy to determine that the loss of so many calories of heat by the water corresponds to the movement of the hand of the registering dial through a certain distance. The ventilation of the animal chamber goes on during the experimental standardising of the instrument just as it would if an animal were in it, and the loss of heat from the water in the coil to the air drawn through is allowed for by taking the temperature of the air as it enters and as it leaves the chamber. It is impossible to take the temperature of the water immediately before it enters the coil or immediately it leaves it, for the tubes leading to and from the coil must pass through the water W, W, W, the air space I, and the air space M, before they can reach the coil. By preliminary experiments allowance is made for this. Now it appears to me that the disadvantages of this instrument are:—1. If there is any error in the original standardising all the results obtained with the instrument are wrong. 2. As allowances are made in the original standardising there may well be some errors in it. 3. Any variation in the temperature of the water jacket will seriously affect the results, and it is a very difficult matter to keep a large mass of water at a constant temperature for a long time. 4. In every experiment all the conditions ought to be the same as during the standardising, but with this instrument this is impossible. 5. In every experiment allowance has to be made for variations in the barometric pressure. It will hardly be disputed that an instrument which avoids all these possible fallacies is more likely to be accurate than one which does not, and therefore I cannot help thinking that the differential instrument I first described can be made to give more reliable results. Further, in general, the differential method is superior to that of primary standardising.

Nebelthau has worked with an instrument which is in principle the same as Rubner's, as it is an air calorimeter, and is standardised before it is used for an animal. It differs chiefly in that the chamber which shows the allowance to be made for variations of barometric pressure is quite detached from the animal chamber. We saw when I was describing the calorimeter I have made that if we want to calculate the whole heat produced by the animal we must include that which does not affect the calorimeter, but is employed in volatilising the water given off in the animal's breath. It is therefore necessary always to estimate the amount of aqueous vapour given off by the animal. This Nebelthau does with a hair hygrometer. I cannot help thinking that this is not so reliable a method as that of absorbing the water with sulphuric acid and pumice, and inasmuch as the heat lost in this way may be a fourth of that produced by the animal it is clear that it is of the utmost importance to estimate it accurately. Nebelthau has made a series of most laborious experiments. He has considered the influence of season, of time of day, of rapidity of ventilation, of moisture in the air, and of the size of the animal upon the heat production; I cannot for want of time stop now to consider the results he obtained, but must pass on to his experiments on fever. He used rabbits and produced fever in them by the injection of cultures of swine erysipelas. He estimated the heat production before and after the injection, and from the results obtained drew conclusions as to the production of heat in fever. He rightly points out the great importance of having the air entering the animal chamber of the same temperature during all the experiments on the same animal, for if it is not some of the variations in the creature's heat production may be due to the variation of the temperature of the air around it. If the air is not of the same temperature Nebelthau following Rubner makes a correction of 2·5 per cent. of the total heat lost for each degree of variation in the temperature. It is clear that if in any fever the rise of temperature were slight, the correction for variations of external temperature might bear a considerable ratio to the alteration in the loss of production of heat due to the fever, and, further, although no doubt the figure 2·5 per cent. was obtained from very careful experiments it is in the present state of our knowledge only an assumption that the figure is the same for all members of the same species. For these reasons I cannot help thinking that it would be better instead of making this correction to ensure that the temperature of the air, and, if possible, its humidity, were the same, at least during all experiments on the same animal. Nebelthau's results are far too voluminous to give in full, but I show you two of them:—

TABLE XX.

Number of animal.	Weight.	Day.	Temperature of rabbit.	Calories. Loss of heat by evaporation.	Loss by radiation and conduction.	Total.	Warmth lost per kilogramme per hour.	Per cent.
	Grms.		Deg. C.					
4	1703	1	39·0	17·75	91·93	109·68	2 683	100
	1625	2	41·7	19·17	109·29	128·46	3·294	122
	1545	3	40·5	18·08	113·64	131 72	3 544	132
7	2327	1	38·6	17·33	106·62	122 95	2·201	100
	2229	2	40·7	20·62	104·32	124·94	2 335	103
	2139	3	40·7	22·52	118·96	141·48	2·756	125

The first point to which he properly directs attention is that no air calorimeter really represents how much heat the animal produces. Air calorimeters are merely large air thermometers which are carefully protected from outside influences, so that any expansion of the air in them must be due to heat given off from the animal, and the amount of this heat lost by the animal is known either because the instrument has been previously standardised in calories by cooling water or because it can be estimated in calories from the hydrogen burnt in the opposite chamber. To obtain in calories the increased heat produced by the fevered animal in a given time (say, an hour) we must know its weight, the rise of its temperature, and its specific heat. (Nebelthau puts this at 0 8, which is, I think, a little too low; 0 95 is probably more accurate.) For instance, to take the first experiment I have quoted, the mean weight of the animal between the first and second days was the mean between 1703 grammes, its weight on the first day, and 1625 grammes, its weight on the second day; that is, 1·664 kilogrammes. Now, the temperature of an animal of a weight of 1·664 kilogrammes and of a specific heat of 0·95 rose 2·7°; therefore, if the loss of heat were unaltered, it must, to have raised its temperature 2 7°, have increased its heat production by 1·664 + 2 7 + 0 95 = 4·268 calories; but we see from the table that from the first to the second day its heat loss to the instrument was increased from 2·683 to 3·294—that is, 0·611 calories per kilogramme of its body weight per hour. Therefore, its heat production must have increased not only the 4·268 calories necessary to raise its temperature from 39·0° to 41·7°, but also enough to compensate for an increased loss in calories equal to 0 611 kilogramme per hour.

Those of you who have followed me so far may be inclined to say that while it appears there are many sources of error to be guarded against if a calorimeter which has been previously standardised is used, yet if the differential calorimeter with hydrogen in one chamber and the animal in another be used, if the temperature and humidity of the air during all experiments on the same animal are the same, and if an accurate means of estimating moisture be employed, we ought to be able to find out from such a calorimeter whether or not the heat production is increased. I am afraid, however, that I fear I shall show you that the difficulties of the subject are not yet

Digitized by Google

ended. The first difficulty we can see by looking at the table I have shown you of some figures obtained by Nebelthau. You will see that in the case of the first animal on the third day it was 80 grammes lighter and its temperature was 1·2° lower than on the second day. Either of these facts would constitute a reason why the creature should give off fewer calories on the third day than the second, but, as a matter of fact, it gave off more. Again, the second animal was on the third day 90 grammes lighter than on the second, and its temperature was the same on both days, yet when it was lighter it gave out considerably more calories than when it was heavier. Now all the instrument does is that it estimates the heat loss by radiation and conduction, because a mass of cooling water in losing a certain number of calories moved the indicator of the recording instrument through a given distance. But the water was losing heat uniformly, and it would be impossible for a mass of water which had decreased in weight and the temperature of which had fallen to give off more calories by radiation and conduction than it did before its weight had diminished or its temperature had fallen. Clearly, therefore, we are not comparing similar processes when we infer the amount of loss of heat from an animal because it moves the registering apparatus of an instrument standardised by cooling water. We cannot tell whether the first animal, for instance, was on the third day, by having altered its power of radiation and conduction, losing heat more rapidly, the production being the same, or losing it still more rapidly with an increased production. The falling temperature at first sight looks like a diminished production, but on the other hand, the increased radiating power points in the direction of an increased production. It is true that when, as in the contrast between the first two days in each animal, the temperature rises and the loss also increases, the production of heat must be increased, but we cannot even then say whether the increased loss of heat is due solely to an increased production, the radiating power of the animal remaining the same, or an increase of both, but the increase of the production being relatively greater, for in either case the number of calories lost would be greater and the temperature of the animal would rise. I am afraid this criticism applies equally to the calorimeter with double chambers, hydrogen being burnt in one and the animal placed in the other. The fallacy is essentially the same in both—namely, we are taking as a standard in both a source of heat (a hydrogen flame or a mass of cooling water) the loss by radiation and conduction from which is dependent solely upon the amount of heat in it, but the animal has the power of automatically altering its radiating and conducting power quite independently of the amount of heat in it, and also has the power of varying from time to time the rate of production of heat in it. These calorimeters measure the amount of heat lost; but as the animal can vary both the rate of production and rate of loss we cannot with them determine quantitatively the variation of production, and this is exactly the problem to be solved in fever. It is true, as I have shown, that we can get qualitative results, and often, as furry animals do not vary much in their powers of radiation and conduction, we can get rough quantitative results; but as man can by vascular dilatation and sweating vary his power of loss by radiation, conduction, and evaporation so enormously, we must be extremely careful how we apply results obtained from calorimetric experiments on furry animals to man.

The next difficulty I have to consider is that due to convection currents. When Mr. Hopkins and I were working at calorimetry we thought the instrument would be more easy to manage if it were so made that the top of it, rather than the bottom, took off, for then the weight of the lid would help to keep it well down in the grease trough. We therefore made such an instrument and suspended the animal from the lid. The hydrogen burners and the inlet and outlet tubes all came through the lid, and the hydrogen burners were so turned up as to make the flame turn upwards. Except for these alterations the instrument was precisely the same as I have already described, but of course it follows that there was no air-space at the top, for the lid contains no air-space; on the other hand, there was an air-space at the bottom. I should add that the position of the animal cages and hydrogen flames relative to the walls of the chamber was precisely the same when the lid was at the top as when it was at the bottom. We at once noticed that the instrument was not nearly so delicate when there was no air-space at the top as when there was one there. It was quite clear, therefore, that we had to deal with some factor, besides radiation and conduction, which influenced the instrument, and this could only have been convection currents. We next turned the instrument back again to its original position with the lids at the bottom, and we found that if a rabbit was in one chamber and no hydrogen burning in the other the manometer moved readily, and also if hydrogen was burnt in one chamber and there was no animal or other source of heat in the other it also moved readily. Further, if hydrogen was burning in one chamber and a rabbit was placed in the other, and the hydrogen flame was kept at such a height that it exactly balanced the rabbit for a few minutes, during which no air current passed through either chamber, and then an equal current of air was drawn through each chamber, then the hydrogen had to be turned up at least 30 per cent. before a balance could be again obtained, and this although no condensation of water due to the burning hydrogen had taken place. This clearly shows that the convection currents from the rabbit and the hydrogen flame are affected unequally by an equal current of air passing through each chamber. It is certain, therefore, that convection currents are a very important factor, and they are different from a minute point like a hydrogen flame, and a considerable surface like a rabbit's body; that this is so anyone can prove for himself by noticing the difference between the feeling of warmth he experiences when he holds his hand over a hydrogen flame and that which he experiences when he holds it the same distance over a rabbit, although the two about balance one another. The importance of convection is also seen by noticing how much hotter a hydrogen flame feels when the hand is held above it than it does when the hand is held equally far off it but at the side of it, although in both cases the radiant and conducted heat is the same, but the hand in the first case meets with more convection currents. This last observation corresponds to that in which we noticed that the instrument is so much more sensitive when the lid is at the bottom and the top is part of the air space than it is when the lid which contains no air space is at the top. When we first began making a calorimeter we tested its accuracy by putting a corked flask of cooling water of a temperature of from 40° to 50° C., but different at each experiment, on cork supports in one chamber and keeping the manometer steady by burning hydrogen in the other, both chambers being shut, and an equal air current drawn through each. When the water was taken out of the chamber its bulk was measured, and its bulk in litres at this temperature multiplied by $\frac{0.9}{1.0}$ gave its bulk at 4° C.—that is to say, its weight in grammes. Its weight in kilogrammes, multiplied by the number of degrees Centigrade through which the water had cooled, gave the number of calories given off by it, and this, together with the small quantity of heat given off by the cooling of the glass of the flask, represents approximately the heat given off by the water to its chamber of the calorimeter. To obtain an exact measure of this heat corrections would have to be made for the specific heat of water at from 40° to 45° and for the period (in all, about a minute) which elapsed between the time of reading the temperature of the flask and the time when it was placed in or removed from the chamber The latter correction, which is small, and a correction for the loss of heat from the glass of the flask were made, but the values given by recent observers for the specific heat of water at about 40° vary from 0·98 to 1 04, a difference of 6 per cent. We were, therefore, unable to make an exact comparison in absolute units between the number of calories given off by the flask and its water and those given off by the hydrogen flame. The following table shows the results of the six experiments (see Table XXI.).

It will be seen that there is a considerable error. At the time these experiments were made we were inclined to the opinion that the cause of this error lay in the fallacies just mentioned, but having since learned the importance of convection currents I cannot help thinking that a considerable part of the error was in each case due to the fact that the convection currents from the hydrogen flame and the water were different. I think there is no doubt, therefore, that because the convection currents from the hydrogen and animal are so different, because they are affected unequally by ventilation currents, and because so much of the effect of a source of heat on the calorimeter is the result of convection, no instrument is satisfactory which does not provide against the errors which may arise from unequal convection currents. I have already shown that the air drawn through the instrument is heated so little, and warmed air gives up its heat so slowly, that I do not think the difficulty would be satisfactorily met by taking the air, leaving the chamber through a spiral tube winding round in the air space connected with the manometer. The error due to convection is probably much less in Rubner's or Nebelthau's instrument than in mine, for it is likely that the convection currents from a spiral coil of warm water are much more like those from an animal than are those from a hydrogen flame, but it would make their instruments more trustworthy if they had been standardised with a coil of water the shape of the animal about to be experimented upon.

To sum up, I think we may conclude by saying:—1. No animal calorimeter that holds out any prospect of being workable can give exactly the amount of heat produced by an animal, for when it shows an alteration in the number of calories lost it does not show what proportion of them have been lost because the creature's radiating power has been altered, and what proportion have been lost because the production has varied, but if we know the variation in the internal temperature of the animal, its weight and its specific heat, we can often say whether or not the production of heat is increased or diminished. In other words, we can get a qualitative but not an accurate quantitative result. 2. As in man alterations of loss of heat probably depend sometimes almost entirely on variation of production, and at other times almost entirely on variations in radiating and conducting power of the skin, we must be very careful in drawing conclusions from animals to man. 3. A differential instrument is very much better than one which has been standardised. 4. But the source of heat in the differential instrument must in shape resemble the animal which is to be observed, and the instrument, before the results it yields can be trusted, be proved to register equally on both sides heat lost by radiation, conduction, and convection. I think it follows that no instrument has yet been devised which gives trustworthy results. I need hardly add that I say this with great regret, for I have for the last six years devoted all my spare time to calorimetry.

Before leaving this subject I should like to remind my hearers of two facts that are frequently lost sight of. The first is that we are too apt to talk of fever as though the process were the same whatever the cause of the fever, while really (as I have shown in the case of man) it is extremely probable that with all animals in some fevers the rise of temperature is chiefly due to variations in the production of heat, and in others it is chiefly due to variations in the loss, and any set of experiments only holds good for the particular animal and for the particular fever under consideration. Secondly, no calorimeter can register heat which is in the body converted into some other form of energy—e.g., motion. For instance, if we were to light a fire in a little locomotive and set it running up a spiral in our calorimeter, the instrument would only register such of the heat as is lost from the locomotive by radiation, conduction, and convection—it would not show that which was produced in the engine but at once converted into motion. If any heat in the living body is converted into motion we have no means of estimating it.

Many attempts have been made to make calorimetrical observations on parts of the human body, and as a rule the results are of little value; but lately Rumpel [2] has published some results which are so very interesting that it will be well to give an account of them. His experiments were all carried out on an arm placed in an air calorimeter for it. From what I have already said it follows that I do not think the results have more than a rough quantitative value. Rumpel shows, by putting first the clothed and then the unclothed arm in the calorimeter, that the loss of heat is greatly diminished by clothing, and he says that Rubner, working with a thermopile, has shown that if the radiation of heat from the naked skin be taken at 100, with a vest on it is 73; shirt and vest, 60; waistcoat, shirt, and vest, 46; and coat, waistcoat, shirt, and vest, 33; and if a guinea-pig's hair is cut off its loss of heat increases 33 per cent. In the first series of experiments a contrast was made between the arm clothed with dry clothes, that clothed with wet clothes, and the naked arm. Table XXII. shows the results.

TABLE XXII.

No. of experiment.	Naked arm gives off calories per hour.	Arm clothed with two layers of dry flannel gives off calories per hour.	Arm clothed with two layers of wet flannel gives off calories per hour.
1	7·92	4·25	—
2	7·41	—	7·45
3	8·39	—	7·96

These figures strikingly confirm the well-known fact that wet clothing is of no use in keeping the body warm. Indeed, it is worse than no clothing at all, for, in addition to the loss by radiation, there is the loss of heat from the evaporation of the water in the wet flannel, which in each of the above two cases was 15 calories, so that the total loss of heat was in the second experiment 7·45 + 15 = 22·45; and in the third experiment it was 7·96 + 15 = 22·96. The arm lost, therefore, when covered with wet clothing about three times as much heat as it would have done if it had been naked. The next experiments proved that the loss of heat in water is much greater than that in air at the same temperature (Table XXIII.).

TABLE XXIII.

Temperature of air or water Centigrade.	Calories lost per hour when the arm is naked in water.	Calories lost per hour when the arm is naked in air.	Calories lost per hour when the arm is clothed but in air.

16·2	103·0	10·9	7·6
20·9	81·0	7·8	5·6
24·7	54·0	7 9	5·0

If to the figures representing the loss of heat to the air we add the loss which is due to the evaporation of the perspiration it works out that at least eight times as much heat is lost in cold water as in air. As might be expected, cold water is worse than wet clothes. In one experiment in which the arm was clothed in wet clothes of a temperature of 20·6° C. the loss per hour was 29·8 calories, but in a bath of a temperature of 20·9° C. the loss per hour was 81 calories. The next table that I should like to quote shows in figures what is, I think, a well-acknowledged fact—namely, that the lower the temperature of the air the more valuable is clothing in saving heat (Table XXIV.). Another interesting table illustrates very well that the addition of clothes diminishes the loss of heat (Table XXV.). It will be noticed that a linen

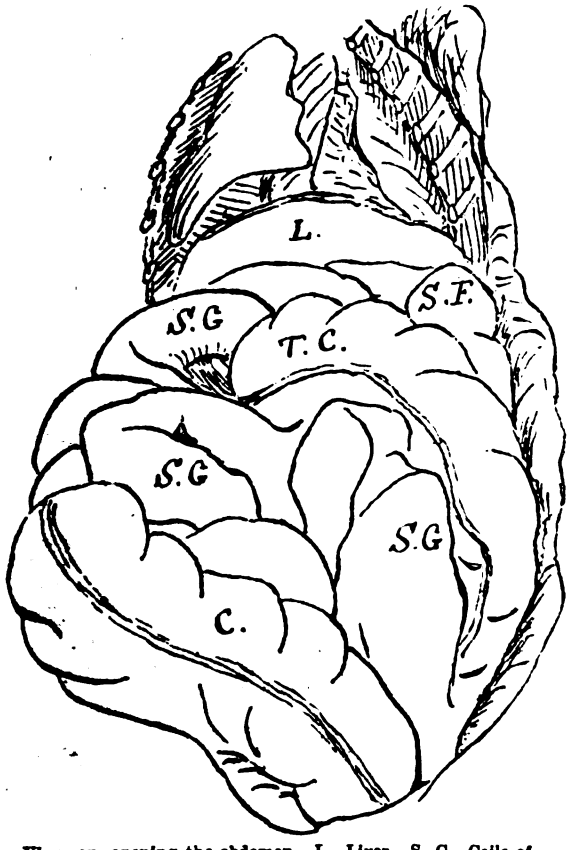
CASE OF INTESTINAL OBSTRUCTION COMPLICATED WITH MALPOSITION, APPARENTLY CONGENITAL, OF THE COLON.[1]

BY FLORENCE NIGHTINGALE BOYD, M.D. BRUX., L.R.C.P. & S. IREL.,
SURGEON TO THE NEW HOSPITAL FOR WOMEN.

A WOMAN, aged thirty-nine years, was admitted into the New Hospital under the care of Miss Walker, M.D. Brux, on Oct. 27th, 1896, complaining of pain in the epigastrium immediately on taking food, followed and relieved by vomiting, constipation and tenesmus with the occasional passage of a small amount of blood, and marked loss of flesh and strength for the last few months. The patient had suffered for six years from indigestion, and for four years had eaten no solid food without pain. For these symptoms she was under treatment at the London Hospital for a period of three months, and in the out-patient department of the New Hospital on two separate occasions. She had been distinctly relieved by treatment, but had relapsed. On admission it was noted in addition that the abdomen was distended and the movements of the colon were plainly visible, there was marked tenderness in the epigastrium, and the respirations were almost entirely abdominal. The patient was put on Salisbury diet without medicine or aperients, and improved very markedly. She took the diet well and ceased to vomit. The bowels acted either spontaneously or by enema. The diet was strictly adhered to up to Nov. 16th, when she had lost weight. It was then modified, and pounded rice and cream were added. On Nov. 25th she had gained weight again, and was so much better and more comfortable in every way that she was allowed to sit up and gradually to resume a less restricted diet in preparation for shortly going out. On Dec. 2nd she was given for dinner a mutton chop, rice pudding, baked apple, and bread. This was followed almost at once by severe pain and much distress, apparently from distension. By 10 P.M. the abdomen was distended and drum-like and the patient was still in great pain. There was no fever. Carminatives were given. On the 3rd the abdomen was a little less distended, but there was still a good deal of abdominal pain. The bowels were open. The temperature was 99·4° F. and the pulse 120. The abdomen moved imperfectly with respiration. On the 5th the patient looked very ill, with drawn and pinched face. The abdomen was unequally distended, chiefly on the right side. She was sick three times, there being typical "coffee-ground" vomit. The bowels were not open and no flatus passed per rectum. The temperature rose to 100° and the pulse ranged between 120 and 130. Rectal feeding was commenced and one-eighth of a grain of morphia was given hypodermically. On the 6th the patient vomited once (vomit of the same character) after the rectal feeding was begun. The tongue was cleaner, the pulse was better (108), and the temperature was 99·4°. On the 7th the patient had a bad night with much pain; she was sick once, the vomit consisting chiefly of mucus with a little brown sediment. I was asked to see the patient in Miss Walker's absence, and found the abdomen distended unequally, and chiefly over the seat of the cæcum, as before; moving badly with respiration. Just above the umbilicus, to the right of the mid-line, on fairly deep palpation between coils of distended intestine a distinct firm mass was felt. This was said not to have been palpable previously. There was no mass in the cæcal region, although the distension was so marked there. I inclined to the diagnosis of a gastric ulcer of the posterior wall, which had perforated into a localised area walled in by adhesions, although this did not account for the cæcal distension, unless the transverse colon were involved in inflammatory matting. Another alternative seemed to be some growth deep in the abdomen involving primarily or secondarily the right half of the transverse colon and partially obstructing it. Hot fomentations were applied to the abdomen and a simple enema was given with no result in either fæces or flatus. Nutrient enemata with brandy were administered. The temperature ranged between 98·4° and 99·2° and the pulse between 108 and 120. On the 8th she seemed a little better and passed some flatus. The abdomen was still much distended in the cæcal region and noticeably flattened in the epigastrium. The temperature ranged from 98·6° to 100° and the pulse from 92 to 108. On the 9th she had much pain through the night. The bowels were open and flatus was passed, but the distension was more general. There was no further sickness. I was again asked to see the patient. There was now clearly to be outlined a rounded mass on a level with, and rather to the right of, the umbilicus, dull to deep percussion, fixed and not tender. On the 11th she was given small quantities of food by the mouth without causing sickness. The abdomen was much distended. The pulse was 120 and less good in quality, and the temperature was below 100°. As she was certainly losing rather than gaining ground Mr. Boyd was asked to see her in consultation. He considered that whether she had a gastric ulcer or not the great distension of cæcum and small intestine indicated obstruction somewhere in the colon, probably about the hepatic flexure, and advised an exploratory incision. The patient was therefore transferred to my care for operation the following morning. She had a better night, and the temperature had fallen from 100·4° to 98·4° in twenty-four hours. On the morning of the 12th the temperature was 97·6° and the pulse was 92°. She had a loose, normal-looking action of the bowels. It had been intended to photograph the abdomen on account of the peculiar and marked distension of the cæcum; but when the patient was placed on the operating table this had so far disappeared as to leave nothing but a moderate general distension. Mrs. Berry, M.D. Lond., gave gas and ether, and I opened the abdomen in the mid-line above the umbilicus. The small intestine, deeply injected and distended, at once presented. There was no exudation. On introducing the hand a tight arch was felt towards the right side, from beneath which was withdrawn a short length of collapsed small intestine absolutely pale from compression, and not more than half an inch in diameter. The mass felt before operation was found to consist of much thickened mesentery in which enlarged glands were felt. The bowel corresponding to this thickened mesentery was drawn out of the abdomen on to hot sterilised towels and carefully examined for growth or ulceration. So far as could be made out it appeared healthy



[1] A paper read before the Association of Registered Medical Women on March 2nd, 1897.

Digitized by Google

though deeply congested. The cæcum was examined and no marked distension was found. The liver was discovered to be pushed up under the diaphragm by the distended intestines and the stomach was completely covered by them. At this point the patient's condition was such that no further search for any primary focus of disease appeared justifiable, especially as the immediate cause of obstruction was thought to have been removed by the release of the compressed coil of gut. So far no adhesions had been found anywhere. The operation lasted three-quarters of an hour and the patient was put back to bed with a pulse of 148. She was almost immediately sick—copious "coffee-ground" vomit—and this continued throughout the next thirty-six hours, the vomiting becoming more and more frequent and the collapse more marked. Ergotin hypodermically and ice to the epigastrium failed to check it. At 12 noon on the day following the operation the bowels acted; there was no blood in the stool. She died at 9 30 P.M. on Dec. 13th, thirty-six hours after operation. The ante-mortem diagnosis was some disturbance of adhesions about a gastric ulcer with secondary septic peritonitis.

Necropsy.—The post-mortem examination was made thirty-six hours after death by Mrs. Flemming, M.D. Lond., pathologist to the hospital. The body was found to be much emaciated. On opening the abdomen the most prominent objects were the much-distended cæcum and the ascending colon, extending from the pelvis along the right side of the abdomen (Fig. 1). Towards the left, part of the transverse

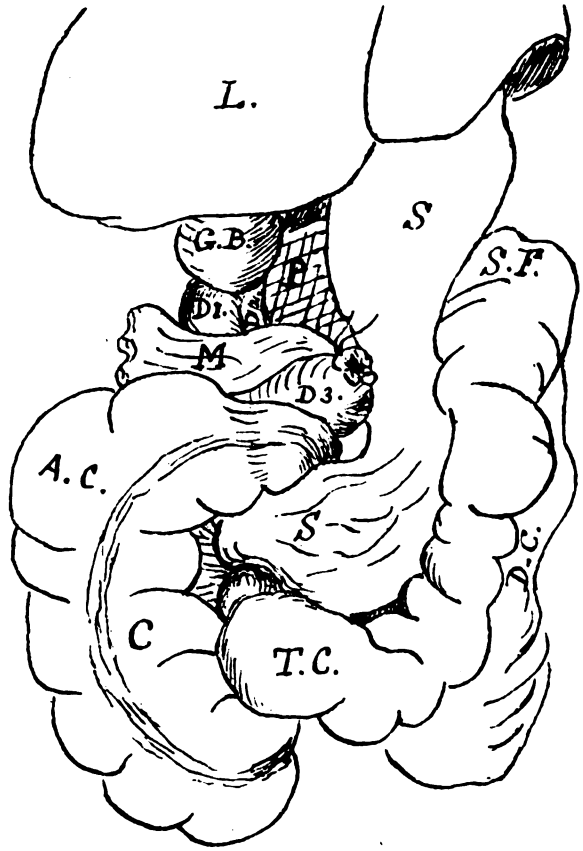


FIG. 1.

View on opening the abdomen. L., Liver. S. G., Coils of small gut, more or less distended and congested. C., Cæcum. T. C., Transverse colon. S. F., Splenic flexure.

colon was seen, and nothing else was visible but coils of small intestine, some being deeply congested. There was no peritonitis. The cæcum could be lifted out of the pelvis and was quite free, being, as well as most of the ascending colon, surrounded entirely by peritoneum; extending upwards on the posterior surface and bound down to it was the vermiform appendix. The liver was completely under cover of the ribs from the fourth to the seventh; the gall-bladder was adherent to the first part of the duodenum. The free cæcum, ascending colon, and the greater part of the small intestine had made a complete revolution from left to right, and from behind forwards. It was this torsioned portion of small bowel that was noted from the first as so congested. Continuous with the lower and left edge of the mesentery was a short, well-marked ascending meso-colon (the cæcum and part of the ascending colon, as above stated, being quite free), which formed the arch felt at the operation. The stomach was pale in colour, of an hour-glass shape, and extending far down into the abdomen. On following it down the pyloric end was found to pass downwards in front of, then upwards and behind, the right end of the transverse colon (see Fig. 2),

FIG. 2.

the two viscera thus constricting one another. The duodenum was next examined; the second and third parts bore the normal relation to the right kidney and pancreas, but the first part, owing to the faulty position of the pylorus, was too long, and ascended vertically in front of the second part (see Fig. 2). The jejunum turned as usual sharply forwards and to the right; the peritoneum covering the first coil was adherent to the peritoneum covering the pancreas. The mesentery appeared at the upper border of the right end of the transverse colon in front of the junction of the stomach and duodenum (see Fig. 2) and to the outer or right side of the colon. The origin of the superior mesenteric artery was normal. The small intestine was now removed. For twelve feet of its extent it was not injected; the remainder was of a purple colour, and the mesentery of this part (the part involved with the cæcum in the volvulus) was thickened and contained swollen glands, which formed the firm mass felt on Dec. 7th, the volvulus having brought it down behind and to the mesial side of the ascending colon, where it was found at the operation. There was a constriction just beyond the dilated hepatic flexure of the colon (see Fig. 2). The transverse colon here passed in front of the vertically placed pyloric end of the stomach and then from above down behind the stomach to gain its normal position

Digitized by Google

with regard to the greater curvature. The splenic flexure was very acute and there were adhesions between the transverse colon as it passed up to the splenic flexure and the descending colon. As the colon thus hooked round the stomach its calibre was diminished, and this seemed to be a cause of chronic obstruction. There was no ulceration of the stomach or intestines. The congested part of the intestine contained dark grumous material similar to that vomited. In relation to the operation the following note was made. No sign was seen in the length of the small intestine of the nipped portion found at the operation. Before disturbing the parts examination was made as to the nature of the arch or hole felt at the operation from which the compressed coil of gut was released. It was found to be formed by the twisted mesentery, dragged down and fixed by the pelvic position and distension of the cæcum.

Remarks.—This case presents features of unusual interest, both pathologically and clinically. The interlocking of the transverse colon and stomach appears to be unique; at least, I have not been able to find a record of a similar case in the writings of Ahlfeld, Toldt, Treves, Lockwood, Kelynack, Talamon, or in Quain's Anatomy. It is difficult to account for such a relation of parts otherwise than by supposing an abnormal intertwining of the stomach and the primary intestinal fold at a very early stage of development. In connexion with this one notes the free position of the cæcum and part of the ascending colon, which no doubt favoured the volvulus that took place later, and which involved also all the lower half of the small intestine. Further, the distension and pelvic position of the cæcum appear to have been the cause of the stretching of the mesentery and meso-colon into an arch, beneath which the small intestine slipped and became compressed. Mr. Treves refers to this possible cause of internal strangulation, but regards it as extremely exceptional where no adhesions exist. In this case there were none, and the cæcum could be pulled up out of the pelvis. Thus there were present three causes of obstruction—narrowing of the transverse colon by pressure of the stomach and interference with the stomach by pressure of the transverse colon; volvulus of a large mass of intestine, to which the engorgement of the mesentery and the grumous vomit were no doubt due; and compression of a coil of small intestine beneath the mesentery, which apparently gave rise to no characteristic symptoms, and which probably was of little importance, as its release gave no relief. If we conclude that the relations of the stomach and transverse colon were of congenital origin, the question arises why the patient should have reached the age of thirty-three years before any signs of hampering of the stomach appeared. The most marked symptom during the last six years of her life was pain on ingestion of food, relieved by vomiting. There was also a fixed tender spot in the epigastrium, and these symptoms were relieved by the ordinary treatment for gastric ulcer, in which, no doubt, a restricted diet and diminution in the bulk of the food passing through the stomach and intestine played a large part. A larger meal than had been taken for some time appeared to induce the final attack, and one inquires to which of the three causes of obstruction were the acute symptoms due. I have stated above that one of these was probably of little importance. I am inclined to think that it was at this early period that the volvulus of the cæcum took place. True, the pain which followed the meal was referred to the stomach, just in the same way as earlier in the case, but the distension, although general at first, later localised itself more distinctly in the cæcum and ascending colon, while the black vomit appeared on the fourth day and the mass formed by the swollen mesentery was detected on the fifth day; at the same time, the greater the distension of the colon became the more did the constriction where the stomach crossed it increase, thus bringing another factor into play. The obstruction, it will be noted, was at no time absolute, and it is interesting that a spontaneous action of the bowels occurred on the tenth day, the morning of operation. In looking back on the case then, one sees in favour of the view that the volvulus was the dominating cause, the sudden onset of acute symptoms, the appearance of signs of engorgement, grumous vomit and a palpable tumour of swollen mesentery, localised distension, and the partial nature of the obstruction. The combination of gastric symptoms, due apparently to chronic compression of the stomach by the colon, with intestinal symptoms was throughout misleading, as was also the varying distension of the cæcum, and it is hardly wonderful that the operation failed to set matters straight when a careful and elaborate post-mortem dissection of the abdominal viscera was necessary to elucidate the true relation of the parts. At the same time I cannot help reflecting that had I succeeded at the operation in recognising and rectifying the volvulus the patient might have been relieved of the acute symptoms and have continued indefinitely her course of chronic indigestion and constipation.

I am indebted to Miss Walker for the earlier notes of the case, and to Mrs. Flemming for the extreme care with which she made the post-mortem dissection. The diagrams given were drawn from the post-mortem specimen before removal from the body. The specimen itself is at the Royal College of Surgeons of England; further examination will, I hope, throw more light on the cause of the malposition, or at any rate on its mode of production.

Harley-street, W.

TUBERCULOUS ULCERATION OF CÆCUM GIVING RISE TO SYMPTOMS OF DISEASE OF THE APPENDIX.

BY HERBERT W. PAGE, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL.

I WISH to place the following instructive case on record, for the simulation of the common symptoms of disease of the appendix was such as to leave little room for doubt as to the nature of the ailment for which the patient had sought relief, and for which operation was undertaken. Nevertheless, the appendix was free from disease, and tuberculous ulceration and narrowing of the cæcum were alone found after death to account for the symptoms. The case is therefore of further value in demonstrating that disease of the cæcum, and of the cæcum only, may cause symptoms likely to be attributed to the appendix, and that positive diagnosis may be very much in error. Happily, increase of experience is adverse to infallibility. In a recent paper in the *Clinical Journal*, entitled "A Demonstration on a Case of Appendicitis," Mr. Lockwood refers to a similar case which had been under his care, where he operated upon a youth who had had what everyone considered to be two typical attacks of appendicitis. When the abdomen was opened it was found that he had acute tuberculous peritonitis, which was localised in the cæcum, in the vermiform appendix, the end of the ileum, and the mesentery. Pain, which had been severe, was entirely relieved by the operation, but the patient ultimately died from acute general tuberculosis. The following is my own case.

A woman, aged thirty-six years, admitted to the obstetric ward of St. Mary's Hospital on Feb. 18th, 1897, gave a history of having suffered from abdominal discomfort more or less for the past eighteen months. In May, 1896, she had an attack of pain in the right iliac fossa, accompanied with vomiting and constipation. Attacks of the same kind, two or three in number, but of less severity, followed at intervals, and in one which occurred shortly before her coming to the hospital a distinct lump had been felt in the iliac region. Uterine and ovarian disease having been excluded, I was asked to see her by Dr. Handfield-Jones, and under anæsthetics we both were able to feel a small hardish lump in the cæcal region. Local indications and history seeming thus to point to disease of the appendix the patient was transferred to my care, with a view to operation as soon as the temperature became normal and quiescence should be re-established after her last attack. With careful dieting and rest in bed this was accomplished, and she became comparatively free from pain. The patient, although emaciated and pale, seemed to be in a favourable state for operation, but I must acknowledge that I did not like the persistent hardness of the lump. There were scars on her neck from old gland suppuration, but there was no present reason to suspect that she was the subject of tuberculous disease. The exploration was undertaken on March 30th, the cæcum being exposed in the usual way and by the usual incision. It was at once obvious that we had to deal with no ordinary condition of things. Adhesions, old and firm, bound a tolerably hard lump which involved the cæcum, the size of a hen's egg, both to the abdominal wall and to the iliac fossa. The appendix was found and removed, but I could see no trace of disease in it, and further exploration

Digitized by Google

had to be abandoned by reason of the impossibility of separating the adhesions. Successful removal of the hard cæcal lump seemed to be out of the question: bleeding was therefore stayed and the wound was closed. The patient went on perfectly well for a couple of days and then without apparent reason began to vomit. Local indications of wrong were markedly absent, but on the third day she suddenly collapsed and died in a few hours without attempt at rally. We suspected perforation, and I deemed it useless to interfere.

I have to thank Dr. Poynton for the notes of an exhaustive post-mortem examination from which the following extracts must here suffice. The cæcum was much ulcerated and thickened by chronic inflammation, and at its junction with the ascending colon was a stricture half an inch in length of almost cartilaginous hardness and so tight as only to admit the passage of a small probe. Circumferential thickening and contraction accounted for this, and section showed that the induration passed into the surrounding areolar tissue after the manner of an infiltrating growth. On the cæcal side of the stricture there was extensive ulceration, and perforation had taken place at a point contiguous to it. No ulceration was found elsewhere. In front of the duodenum, in the position of one of the meso-colic glands, was a gland of the size of a small flattened orange, which on section presented the aspect of caseous material, but was not soft. Another smaller gland lay close beside it. There was an old scar just below the apex of the right lung. Microscopical examination of the several diseased parts was made, and the appearances in the gland very strongly suggested tuberculous disease in the neighbourhood. The bowel showed chronic inflammation, without sign of either sarcomatous or carcinomatous growth, and although not definitely tuberculous it was almost certainly of this nature. The stump of the appendix showed nothing more than some inflammatory thickening. Commenting on the notes Dr. Poynton remarks: "The case would appear to be one of chronic tuberculous ulceration of the colon and its junction with the cæcum resulting in stricture, with secondary ulcers, which, from the slight amount of induration, were perhaps not tuberculous, but the result of the obstruction. The glands were affected in the same chronic way."

There is, of course, nothing very uncommon in this condition of things discovered after death, but in its surgical aspect the case appears to me to be worthy of record.

THE VALUE OF AN EXCLUSIVE RED MEAT DIET IN CERTAIN CASES OF CHRONIC GOUT:

A CONTRIBUTION TO THE STUDY OF AUTO-INTOXICATION.[1]

BY WILLIAM ARMSTRONG, M.R.C.S. ENG.

ABOUT seven years ago I saw two patients, one suffering from severe chronic gouty arthritis and the other from recurrent uric acid calculi, in both of whom, after all routine treatment had failed, cure was effected by the so-called "Salisbury" treatment, prescribed and directed by a lady. Taking for many weeks nothing but red meat and hot water, these patients certainly made wonderful improvement, which, in spite of a gradual return to an ordinary dietary, persists to this day. It seemed to me that this treatment possessed some element of usefulness, but that it ought neither to be used indiscriminately nor without medical guidance. The only English book on the subject, which quickly obtained and still has a large circulation among the laity, was written in a tone and spirit which did not encourage the medical profession to give this method a thorough trial; but the patients whom I had tried in vain to help, and for whom I had sought the best special advice without good result, were so evidently benefited that I have since then given this diet a careful trial, more especially during the last three and a half years, when I have been afforded in Buxton exceptional opportunities for selecting suitable cases for its use and for watching its effects. The indefatigable and painstaking work of Dr. Alexander Haig and the careful and ingenious experiments of Dr. A. P. Luff, which latter, placed before us in the recent Goulstonian Lectures,[2] have excited so much interest, indicate that the red meats or their salts are in themselves harmful to the gouty. Having for the last three years been working on the subject of auto-poisoning in relation to the causation of gout, some forms of rheumatoid arthritis, and allied ailments, I had been led to doubt whether that is so, or whether it is not the admixture of food of other classes with the red meat which causes complex chemical changes leading to the formation (whether in the blood, tissues, or kindeys) of an excessive quantity of uric acid. The able and suggestive work of Dr. Lauder Brunton has done much to stimulate medical opinion on this subject, and has given us a better understanding regarding the chemical changes which take place during digestion and their clinical significance; while the researches of Gautier and Bouchard have added to our knowledge of "the self-poisoning of the individual."

The course of treatment, which lasts from four to twelve weeks in its strict form, is as follows—subject, of course, to such modifications as the condition of the patients and their progress demand. The bowels having been thoroughly relieved the patient begins to drink from three to five pints of hot water daily; the temperature of this should be from 100° to 120° F.; a little lemon juice may be added, and it should be drunk in sips. One pint should be taken at least one hour before each meal, and the same quantity at bedtime. The food should consist at first of beefsteak from which all fat, gristle, and connective tissue have been removed; this should be thoroughly minced, a little water being added, and then warmed through with gentle heat until it becomes brown in colour and perfectly soft and smooth; it can be eaten thus or else made up into cakes and cooked on the grill. On the minced meat may be put the poached whites of from two to four eggs per day. The only bread allowed is a half slice, cut very thin, and thoroughly torrified in the oven, with each meal. A little salt or pepper may be added to the meat, or a little mustard freshly mixed with lemon juice. As the treatment progresses a little of the steak may be given grilled, or a lean mutton chop; very little or no fluid should be given with the food. The quantity of the meat given is from one pound to four pounds in the twenty-four hours. During the latter part of the treatment a grilled cod-steak is often ordered. Alcohol should be avoided; if absolutely necessary a little good whisky with cold water may be given with food; or a cup of weak tea with a slice of lemon, or a cup of black coffee may be taken. The immediate results experienced are a feeling of hunger and a difficulty in drinking so much hot water; these difficulties soon disappear, although the feeling of "emptiness" due to the stoppage of the carbohydrates often persists. There is also a marked diminution of the abdominal girth and a more or less rapid loss of flesh, especially in those who are fat and flabby; but walking is much easier and the breathing is often greatly relieved. The urine at first is often scanty and loaded with urates, which indicates either the necessity for adding some freshly prepared citrate of potash to the hot water given in the early morning and late evening, or else an increase in the quantity of water drunk. The bowels become constipated, the motions being scanty and dark coloured. An aperient is often necessary. After the first two or three weeks the patient begins to feel weak and easily tired, and it is wise at this stage to limit the amount of exercise taken, substituting in some cases a little massage; but before the conclusion of the course the strength returns, and stout patients especially feel the benefit of the diminished weight.

The changes due to the treatment are very marked. The swelling of the joints diminishes, the aching and soreness are greatly relieved, and the mobility is considerably increased. The patient becomes brighter, and work, both mental and bodily, is done with pleasure instead of with trouble and effort; acidity, pyrosis, heaviness, distension, and oppressed feelings after food disappear, flatus is greatly diminished in quantity and becomes much less offensive, and the perspiration loses the disagreeable odour so frequently present in these cases. The urine becomes more copious and clearer, and does not give the reactions to nitric acid and ferric chloride mentioned later, and the oxalates and uric acid are materially decreased. The indications for

[1] A paper read before the Medical Society of London on April 26th, 1897.

Digitized by Google

the adoption of this treatment seem to me to be: (1) obstinate and refractory chronic gouty arthritis; (2) recurrent uric acid calculi; (3) frequent and intractable migraine; and (4) obstinate gouty dyspepsia. The treatment appears to be indicated more especially if any of the following symptoms are present: (*a*) amylaceous and intestinal dyspepsia; (*b*) acidity, pyrosis, and flatulence; (*c*) heaviness and irritability after food; (*d*) excessive formation of sulphuretted hydrogen in the large intestine, disagreeable smelling perspiration, and offensive breath; and the following conditions of the urine: (*e*) persistent lithiasis; (*f*) oxaluria; (*g*) excessive formation of indican; (*h*) purple or red reaction with nitric acid; and (*i*) wine-red reaction with ferric chloride.

I am sure that where either damaged kidneys or a weakened heart are present exceptional care should be taken; in fact, many of these cases are quite unfit for the treatment. I do not say all, advisedly, as I have seen several cases in which both unsound kidneys and heart have been greatly relieved, but such patients require daily watching and the exhibition of great care, experience, and discretion. The above mentioned symptoms, I would venture to submit, bring us face to face with the great question of auto-poisoning. I have been greatly impressed by the sudden subsidence of severe chronic gouty arthritis in five cases. In three of these it followed what were described as "very severe bilious attacks"; and in two it came on after severe and spontaneous attacks of diarrhœa; the relief was immediate and complete, and for several weeks the patients kept better, but gradually the old symptoms began to return, and in three months after the sudden improvement they were as bad as ever. No doubt also many of us have observed how severe attacks of deltoid rheumatism of many weeks' standing have been at once removed by a mercurial purgative. These facts seem to me to point to the possibility of poisons generated in the alimentary canal setting up affections of the joints. Bouchard describes certain articular enlargements which he contends are almost always present, more or less, in cases of gastric dilatation. That a very considerable number of ptomaines, leucomaines, and toxins are formed in the alimentary canal seems to be beyond doubt, as is also the fact that they are taken up by the blood and appear in the urine. A most important discovery was made by Gautier in 1885, when he found that poisonous alkaloids were continuously being formed in healthy men and animals by decomposition in the intestinal canal during the process of digestion or in the blood and tissues generally by the metabolism which occurs during the functional activities of life. It seems to me that if we have either an excessive formation or a deficient elimination of these toxic products we get a condition of self-poisoning, which may be either slight and transient, severe and lasting, or, what I believe to be more common still, a daily storage of small quantities of noxious matter which gradually undermines the health, leads to deterioration of the nervous system, and disturbance of the nutrition of some or all of the structures of the body; and it seems likely that vital action is much more quickly interfered with through the accumulation of waste products within the organs than by any want of nutriment of the organs themselves. Aitken, writing on gout and rheumatism, says: "They are such diseases as become developed under the influence of agents generated within the body itself through the continuous exercise of its functions in the daily course of nutrition, development, or growth." That marked symptoms of poisoning do not more frequently occur is due to the physiological processes continually going on in our bodies: (*a*) the elimination of the poisons by the kidneys, liver, skin, lungs, and the lining membrane of the bowels; and (*b*) their destruction by oxygenation, the leucomaines being burned up in the blood. That the urine contains toxic products was made clear by the researches of Mr. Reginald Harrison, our esteemed President, concerning so-called "catheter fever" when he gave his adhesion to the following important conclusions: (1) In health alkaloids exist in the living subject; (2) these arise in the intestinal canal through the action of putrefactive intestinal organisms; (3) the alkaloids of normal urine represent a practical part of these alkaloids absorbed by the intestinal mucous membrane and excreted by the kidneys; and (4) diseases augmenting intestinal alkaloids augment in consequence the urinary. Dr. Lauder Brunton suggests that one set of poisons is probably allied to uric acid, and includes guanidine, methyl-guanidine, xanthine, and other derivatives of urea. A very interesting statement has been made that while the greatest part of the products of albuminous waste is in health secreted by man in the form of urea with very little uric acid, in disturbance of nutrition (as by self-poisoning, affections of the nervous system, &c) the quantity of uric acid is enormously increased. It has also been suggested that as pyrocatechin, a body of the aromatic series frequently found in urine, is known to have a poisonous action on the spinal cord it may probably interfere with the joint centres, an thus set up reflex trouble in the articulations.

To those who entertain the opinion, so generally held, that the various toxins are formed from the decomposition of animal food it will not be at all clear how a meat dietary, even with the aid of hot water, can alter this condition; but Brunton and Macfadyen have shown that "the same bacteria which form a peptonising enzyme on proteid soil can also produce a diastatic enzyme on carbo-hydrate soil"; and, further, that "the same bacilli, when grown in starch-paste instead of in gelatin or in beef-tea, produced a different ferment, which would convert starch into sugar, but which would not act upon gelatin." Bouchard, again, strongly condemns bread, with the exception of the outer crust, on the ground that the process of baking, although it has interrupted the fermentation, has not stopped it altogether, and that this fermentation re-appears when moisture and temperature are again favourable to it, and from this are formed acetic and butyric acids, leucin, tyrosin, and phenol in large and poisonous quantities. The difficulties of a mixed diet of meat and carbo-hydrates in the gouty state are that the latter are so much more easily oxidised, and are therefore more readily consumed in the system than the albuminous compounds, and thus prevent the disintegration and oxidation of the latter; and also that vegetable albumin less easily undergoes disintegration than animal albumin. In gout disintegrative changes in the albuminates are arrested, and insufficiently oxidized substances remain in the blood; and in this connexion it is of importance to note that under a diet of animal food more oxygen is retained in the system than when starchy foods are taken in excess. The microbes subsisting on starchy food, milk, and cheese may be got rid of by a purely meat diet and *vice versâ*, the offending microbes being starved out.

I would now ask the question whether, from the foregoing facts and theories, it is possible to suggest any scientifically satisfying reason for using this dietary. And in reply I would submit that meat taken as suggested is easily and readily digested; that the process of digestion is more complete and perfect, and is almost entirely free both from the processes of fermentation and putrefaction and from the toxic products thereof; and also that there is a more complete oxidation of the food taken, and therefore less waste and morbid material remaining in the system. Whatever poison does remain is more promptly eliminated by diuretics than by any other means, and no diuretic is more efficient than a free supply of water, especially when taken into a comparatively empty stomach. The exceptional power of water as an eliminator has been well shown by the researches of Sanquirico into the lethal doses of various drugs. There can be no doubt also that water has a direct flushing effect on the stomach, kidneys, and liver. It has been suggested to me that, while a very much improved condition of the general health might be brought about by the stimulating effects of a diet of red meat, the uric acid in the system would be driven into the joints to their great detriment, and that when this diet was discontinued most serious relapse would occur, the last state of the patient being much worse than the first. I have watched this point most carefully, and in a number of cases I have gradually brought the patient down from a meat diet to a carefully arranged mixed dietary, and in eight cases still further to the meat-free dietary recommended by Dr. Alexander Haig, without any such result being observed. Had space permitted I should like to have submitted the detailed notes of cases of chronic gout and recurrent renal calculi treated by this method. In some respects the latter cases are the more interesting, for in spite of the continuous taking of solvents they were, up to the time of taking this dietary, frequently passing uric acid calculi. With the exception of a few small stones passed shortly after the commencement of the treatment (in less than half the cases only) no further formation took place, although the use of all solvents was discontinued.

My experience of the so-called "Salisbury" dietary has led me to form the following conclusions, which I venture to submit for consideration and criticism: (1) that a certain

Digitized by Google

number of cases of chronic gouty arthritis, recurrent uric acid calculi, and gouty dyspepsia, with fermentative changes, which have proved refractory to ordinary methods of treatment and dietary, may be treated by means of an exclusively red meat dietary, *plus* hot water drinking, with excellent results; (2) that this method of treatment is irksome and trying, and as, unless it is carried out strictly in the first instance, it is apt to do harm it should only be used in those cases where other methods have failed or are thought likely to do so; (3) that the cases require careful selection and close medical supervision, the details being modified according to the needs of each individual patient; (4) that those who suffer from persistent albuminuria or organic heart disease are in most instances unfit for this treatment—when, however, it is prescribed for them its course should be watched daily; (5) that certain cases of chronic gouty arthritis which fail to improve while on a mixed diet recover equally well whether on this dietary or on the meat-free dietary suggested by Dr. Alexander Haig; (6) that it is of the utmost importance that no addition, however small, of carbohydrates, saccharine matters, or fruit be made to the dietary during the first few weeks of treatment, very slight acts of carelessness in this respect having often caused disappointment and failure; and (7) that used with due care and discretion this method is a most efficient, and sometimes even a brilliant, addition to our therapeutic resources, but that it is only necessary in some 3 or 4 per cent. of gouty cases treated.

Buxton.

ON THE CONNEXION (IF ANY) BETWEEN MENTAL AND NON-PUERPERAL UTERINE DISEASES.

BY JAMES BRAITHWAITE, M.D. LOND.,
OBSTETRIC PHYSICIAN AND SURGEON TO THE LEEDS GENERAL INFIRMARY.

MY attention was drawn to this subject by the following case. A single woman had spasmodic dysmenorrhœa of a very severe type. Her own medical attendant, who was a homœopath, not having given her any relief, she came to me as long as eight or ten years ago. I found her to be a delicate woman with some traces of old tubercle in the right apex. I dilated the cervix moderately, as I found that all medicinal treatment was useless. This dilatation gave her great relief from the pain, but it was only temporary, and in three months' time the pain was as bad as ever. The uterus was what I call "a sitting-down womb," as the sound first passed forwards, then backwards a little, and then forwards again. At her request I re-dilated the part, but did it extremely thoroughly, passing a laminaria tent the first day and dilating successively by Hegar's and Reid's dilators on the second and third days. The canal would then admit an index finger. This permanently cured the dysmenorrhœa, and the patient remains to this day perfectly well as regards this disease. Some years after this other symptoms led to a re-examination, when retroflexion was found. As the patient apparently suffered from this displacement it was rectified by a Hodge's pessary, No. 1 size, as the vagina was very small. This answered extremely well, and the periods, which had been rather profuse, became quite normal in amount. I again saw nothing more of her for some time, except that at regular intervals of about eight months I inserted a fresh pessary. In the autumn of 1896 she had begun to be in a desponding mental condition. She was, to use her own words, "unutterably miserable." Nothing could overcome her dejection of spirits. She was perfectly sane, and talked reasonably, but hopelessly, of what she called her unaccountable misery. In her letter to me she used the following expression: "The miseries of this extraordinary illness are breaking my heart." I will not say here what I thought was the real cause, or what I recommended in the treatment, as the patient went up to London on the advice of a relative and consulted a London physician, not, however, a gynæcologist. He at once made a vaginal examination without removing the pessary, if the statement of the patient is to be relied upon on this point. He made her "breathe down," to use her own words. He then told her that the cause of her mental condition was the state of her womb. He did not treat her himself for this, but sent her to a well-known electrician and gynæcologist. This gentleman recommended electricity and baths in the treatment. He wrote to her mother, and the following sentence is taken from his letter: "The local condition is a hardened condition of the womb due to the bend, for which the dilatation does but temporary good. Electricity followed by the baths will, I believe, certainly allow of a complete cure." The patient then returned home to consult with her mother, and I was sent for and told about the opinion which had been given, and was shown the letter from which I have quoted. The next morning I examined the patient carefully myself. There was absolutely nothing abnormal, the uterus was in good position, there was no flexion or displacement of any kind, and the roof of the vagina on every side of the uterus was perfectly soft and normal. I may here say that I believe the physician who first examined her was perfectly honest in the opinion he gave her—that the mental condition was owing to some uterine disease. He did not verify this by his vaginal examination, as he did not remove the pessary. He seemed to think that such a condition must *necessarily* arise from uterine disease. With regard to the letter from the gynæcologist, it will be noticed that he referred to the dilatation, and said that this did but temporary good, whereas it made an absolute cure of the dysmenorrhœa. The bend referred to in the letter did not exist at the time I dilated for dysmenorrhœa, nor did it exist at the time of his examination, for I examined her myself a few days afterwards, and there was not the least trace of flexion, and there had been no flexion for at last eight months previously, when I last changed the pessary. He must only have inferred that there was a bend because he found a Hodge's pessary in the vagina. The real cause of the mental condition I believe was as follows, and this is also the patient's own explanation. In the summer of last year she had an attack of syncope at a menstrual period, not from pain, but simply from debility. She fell down upon the ground, as she was standing at the time. The next month she expected another attack, and she thought it possible that at any time she might fall down in the street. The dread of this kept her confined to the house and in a state of mental misery. I had recommended her to be sent from home to Cornwall or Devonshire in order that she might have frequent change of scene and air. When asked my opinion about the proposed electricity I said to the mother, the daughter not being present, that although I entirely disagreed with the idea that the mental condition was caused by a hardened condition of the womb, because no such hardened condition existed, and the case could be easily explained by the mental anxiety caused by the dread of another attack of syncope, still, I would not dissuade them from the electrical treatment, as the season of the year was winter, and the complete change of scene to a London nursing home, with the feeling that something great was being done for her, would probably act almost, if not quite, as beneficially as my plan of a tour in the South of England. The patient accordingly went to London and had electricity applied three times a week for five weeks, and then five times at rather longer intervals. She then went to Brighton for three weeks, and returned home about the middle of April perfectly cured as regards her mental condition. I feel absolutely certain that the electricity merely acted in the way I have named, and possibly the remedy is thought more of when it is very expensive.

This case it is which has drawn my attention to the subject which forms the title of this paper, especially as the physician who first saw the case in London, according to the patient's account—and I have nothing else to rely upon, for I have not had any communication from him or from the electrician—at once came to the conclusion that such a mental condition must be necessarily uterine in origin. A few years ago I altered and improved my plan of indexing my private cases. Since then I have full notes of about 2000 gynæcological and obstetric cases, the latter, however, being relatively few in number. I therefore at once referred to my index, and I have not one case at all like that which I have described, but I do not include in this cases of puerperal origin. A great many of the patients with retroflexion complained of curious feelings in the head, often described as a weight on the vertex. There are also a considerable number of cases of menstrual and inter-menstrual neuroses, often of a very severe type, but unattended with any mental affection. I must make, however, an exception to this statement, as I had one case of a girl who was overworked at school; menstruation ceased, and the girl ceased to speak or take any notice of anything around her. She

Digitized by Google

was not insane. This appeared to be simply mental and physical exhaustion. After about two years' treatment this girl is again beginning to menstruate, and she is able to answer questions.

On referring to perhaps what is one of the best works on mental diseases—that of Mr. Bevan Lewis—I find he makes no reference whatever to any connexion between uterine and mental diseases. He says, however, that there are two forms of insanity connected with menstruation—the first known as climacteric insanity, accompanied by gloomy forebodings, especially of a religious nature; the second known as the insanity of adolescents, characterised by religious exaltation. These cases, however, come to the mental physician and not to the gynæcologist. On looking over my notes of infirmary cases, which are also well indexed, I find I have had one case bearing upon the subject. This woman, who was thirty-four years of age and unmarried, suffered from the most intractable retroflexion along with mental depression of a severe type. No Hodge's pessary would keep the uterus in position, and I have a letter from a gentleman who saw her once or twice only, and who recommended that the operation of ventro-fixation should be done. He attributed her mental and neurotic symptoms to pressure on the ovaries by the flexed uterus. I performed this operation for her in the Leeds Infirmary on Jan. 21st last, and have no doubt that the uterus still remains in good position. I received, however, a letter about two months ago in which the patient's mother stated that her mental condition remains just as before. At the time of the operation I ascertained that the flexed fundus just touched the left ovary without pressing upon it, the ovary being to the outer side of, not behind, the fundus. The right ovary was not touched at all. My verdict, therefore, in the whole matter is that there is very little connexion, and only in rare and accidental cases, between genuine mental affections and ordinary non-puerperal uterine or ovarian diseases, but that there are any number of cases of neuroses of various kinds. In other words, the sensory portion of the nervous system, but not the thinking part, is liable to be upset. At the same time it must be remembered that there are often two points of view from which the same subject may be regarded, and taking it from the mental physician's point of view there is more evidence of a connexion between the two diseases. Dr. Charles Hood, formerly resident physician of Bethlem Hospital, in one of the decennial statistical reports of that hospital, says, when the process of menstruation is insufficient and painful, that there are often symptoms which may be said to foreshadow insanity—an irritable and quarrelsome disposition, a marked waywardness, a disposition to despond, and so on; and these symptoms are still more marked where the menses are altogether suppressed. Amenorrhœa, there is reason to believe, is frequently one of the causes of insanity; certainly, the menses are often suppressed in insanity, and their re-appearance is often contemporaneous with recovery. He then gives some statistics, but these are quite unreliable for my purpose, as cases of aggravated hysteria and those originating in puerperal mania and over-lactation are included. Dr. Hood concludes his review of cases of insanity from all sources with the following sentence: "The only general conclusion which can be drawn from a consideration of the causes of insanity is that they are more or less obviously of an exhausting or depressing character, a conclusion which shows indirectly what is now generally allowed, that insanity is a disease of depression, exhaustion, and irritation." It seems to me that it is only in this indirect way that there is a connexion between mental and non-puerperal uterine disease.

Leeds.

AURAL HYPEROSTOSES.

BY GEORGE P. FIELD, M.R.C.S. ENG.,
AURAL SURGEON TO ST. MARY'S HOSPITAL.

As regards the subject of aural hyperostoses, to which I have for some years past devoted a considerable amount of attention, I would urge on all practitioners the desirability of taking careful note of all cases that come under their observation. It is true that these growths are the reverse of common, but they are of great pathological interest, and the complications to which they give rise may be most serious. During last year I operated on nineteen patients with aural exostoses. That of these only one was a hospital case seems to me inexplicable, unless it is due to the prevalent dislike among the poorer classes to contact with water; for, as I first pointed out many years ago, and my surmise has been repeatedly borne out by the histories of my patients, cold water may be looked upon as a usual factor in the production of these growths. My attention was earliest drawn to this point by their occurrence in three men—I have now operated on all of them for double exostosis—who were accustomed to bathe together in the sea twice a day.

The expectant treatment of these ivory-like excrescences is attended with much risk because not only do they increase insidiously to a large size, filling up the meatus, but they also, by pressure on its bony wall, give rise to painful inflammation, and the attendant pus being pent up behind the growths may cause severe brain symptoms and may lead to the death of the patient. I well remember two cases in which, although I strongly urged the necessity of operation, pointing out the hazard of delay, active interference was deferred to a more convenient season, as other advisers had maintained that the exostoses might "atrophy," the outcome being death in both instances before help could be given. I have removed aural exostoses both by chisel and by dental drill, and after a large experience have unhesitatingly decided in favour of the latter, as I have never witnessed a single failure where it has been employed. One striking result of the operation is that the benefit received is lasting—i.e., there is no recurrence of the obstruction, so that a favourable prognosis in case of removal is always fully justified. Thus the three men before alluded to are all perfectly well at the present time. The return of hearing after operation for exostosis may be delayed for six or eight weeks by persistent granulations in the meatus. These should be carefully removed with fine forceps; silver nitrate can then be applied on a probe. Subsequently a spirit lotion with boracic acid and glycerine should be used.

For this paper I have selected records more particularly of cases of medical men, as their testimony appears to me to be professionally more valuable than that of other persons. Incidentally in my recital will be observed additional confirmation of my theory that aural exostoses are occasioned with comparative frequency by the practice of bathing in cold water.

CASE 1.—I received recently from a medical man the following summary of his own case: "I consulted an aurist some years ago and he told me I had an exostosis in either ear, and that if it got worse I should do well to place myself under your care. In my youth I went in for diving a great deal and remaining under water for a long time. In later years I used to get deaf whenever I caught cold, and latterly on three occasions had a dull pain in the ears. When I consulted you eighteen months ago you told me that the exostoses were marked, and on my return from Egypt last year I submitted to a double operation at your hands. I was more or less deaf for two months afterwards—while, in fact, the granulations remained. After that time my hearing returned, and it is now as good as ever it was."

CASE 2.—Early last year I operated on a medical man in practice for large ivory growths in both ears. He had become so deaf that his continuance in practice as he was would have been quite impossible. After the operation he regained his hearing. There was nothing noteworthy in his case except that he also had been in the habit of bathing constantly in cold water. He had never been the subject of either gout or syphilis.

CASE 3.—A patient was sent in March, 1896, by Dr. Ferrier to consult me, and is remarkable for the age of the patient, which was only twenty-two years. In 1892 he first noticed irritation of the ears after bathing frequently. When I saw him both ears were occluded by large exostoses. After my operation on March 24th he remained at a surgical home for three weeks. He came again to see me on April 30th last, and he could then hear perfectly well with both ears.

I received communications a few weeks since from the first and second of my patients of the bathing trio already referred to. The first reports himself thus: "My hearing in both ears is excellent. I can use the stethoscope and hear a watch at arm's length. I suffer no inconvenience; I am, however, careful in bathing to protect my ears when under water, as you thought that bathing had possibly somewhat to do with originating the growth of the exostosis. It was at the end of the year 1877 that I was under your care, so that you operated on me now nearly twenty years ago." The

Digitized by Google

other patient says: "I have had no return of deafness since the last operation. I can hear equally well with either ear and can use a stethoscope as well as ever. I consider my hearing is as acute at present as it was before the growth of the exostoses."

CASE 4.—From yet another medical man I have received the following: "I am thirty-seven years of age and have, I believe, a slight gouty-rheumatic diathesis. About the middle of February, 1896, coming down the East African coast from Durban, I suffered suddenly from great pain alternating in both ears, with almost complete deafness. I had never suffered from deafness before this sudden attack, but for some time back, say, fifteen years, I had been susceptible to draughts at night time, waking up occasionally with a slight pain in the ear exposed. At Cape Town I was examined and both ears were found constricted, apparently by some growth, the constriction being aggravated by a highly inflamed state of the mucous membrane. Palliative measures were adopted, to which the inflammatory condition yielded, and before reaching Southampton on March 14th I had quite recovered. But I was aware that there was something radically wrong, and I consulted a surgeon, who diagnosed exostoses in both ears, and prescribed an ointment to be painted on the growths at specified times. This treatment I pursued for a month, with what result I am naturally unable to state. At that time I happened to describe my condition to a brother practitioner, and he, having examined the growths, strongly recommended me to see Mr. Field. He pointed out that the growths would most probably not decrease in size, and that I should be at any time liable to a similar inflammatory condition with its accompanying deafness. On April 17th I consulted Mr. Field, and he at once decided to drill out the growths. The operation was performed on April 21st. I was under anæsthesia for, I believe, nearly three-quarters of an hour. I suffered no pain and very slight discomfort. I left the private hospital on May 4th, having walked out with a protection to my ears for three or four days previously. In my case the granulations were particularly exuberant, and a slight discharge continued till the end of May, accompanied by deafness. The deafness was much relieved on my return from a short trip to Hamburg on June 22nd, and on July 2nd, when I last saw Mr. Field, it had entirely disappeared. I have been passionately fond all my life of bathing, and have lived in the water whenever possible. I have never taken the precaution to put cotton-wool in my ears."

CASE 5.—A patient, aged sixty years, was sent to me by Dr. Henry Green. There was a history of bathing in cold water, but, curiously enough, the ivory growth was in only one ear, the left. As there had been loss of hearing in the right for many years it was very important to obtain relief. I drilled in May, 1896. His hearing did not return for two months, for granulations in the meatus, the most annoying obstacle in the treatment subsequent to operation, were extremely persistent. However, after treatment with saturated solution of silver nitrate, applied by means of wool twisted on a fine probe, they by degrees disappeared, and audition in the left ear was completely regained.

CASE 6.—A patient, aged forty-seven years, another sufferer from exostoses, was sent to me by Sir William Broadbent. He had been deaf in the left ear for many years owing to an abscess, and both this and the other ear showed ivory growths when he consulted me. As he was in a large way of business it was of the utmost importance to him to recover his lost sense. He thus describes his case: "You performed the operation in March, 1896. Neither ear gave me any actual pain afterwards. The left ear is still deaf, and always has been so, but in the right I have regained my hearing." The granulations were troublesome also in this case, but were treated successfully in the way just referred to.

CASE 7.—In May, 1896, I operated on a man, aged forty-four years. The right tympanum had been destroyed by scarlet fever during babyhood. Hearing in the left was acute till near the end of 1895. This patient suggests that, as his father was always deaf in the right ear, and for some years in both ears, the exostosis from which he, the son, suffered may have been inherited. He confesses, however, that when about twenty-nine years of age, he bathed daily during six months, and that he generally had a little sea-bathing every year in the summer, floating a good deal without wool in the ears.

CASE 8.—In the case of a man on whom I operated in September, 1896, there was an ivory-like growth in the left ear only. There was but slight pain after treatment, and that merely for a short time on the third night, and recovery was complete within seven weeks.

In conclusion of what I have at present to say on the subject of aural exostoses, I will briefly refer to two instances of a pedunculated growth in one ear, and not the usual broad-based ivory-like mass.

CASE 9.—A man, aged thirty-six years, was sent to me by Mr. Hearnden, of Leatherhead. I followed with him the procedure I have found best in such cases—namely, to drill through the tumour at its base and then to seize and extract it with dentist's fine stump forceps. A year after the operation I received the report: "I have not had one moment's discomfort or any difficulty in hearing since I left your hands."

CASE 10.—The other patient, a woman, I had in the surgical home at the same time as the last. Pedunculated aural exostoses, I should mention, are very uncommon in women and are generally confined to one ear. I have never in hospital met with an instance among female patients, and I can remember a total of but five altogether. Of true ivory exostoses I have as yet seen no example among women, possibly because, as they object to wetting the hair, their ears are seldom exposed to a flow of cold water.

Wimpole-street, W.

DISTRICT NURSING ON A PROVIDENT BASIS.

BY JAMIESON B. HURRY, M.A., M.D. CANTAB.

IT was a singularly happy decision of Her Majesty's to devote the Women's Jubilee Offering of 1887 to the encouragement of district nursing of the poor in their own homes, and the nation will ever be grateful for that wise and unselfish gift, which has given such an impulse to district nursing and indirectly has brought comfort and relief to thousands of the suffering poor. This memorable year of 1897, with its celebration of the Diamond Jubilee, will give a further impulse to the movement, since in many parts of the country district nursing has been selected as the form of memorial most likely to benefit, both now and in the future, our large wage-earning population and to remind generations yet unborn of Her Gracious Majesty's never-failing sympathy with the suffering and poor.

The present occasion is therefore an opportune one for the inquiry—Has district nursing been organised on the wisest basis? Has it been made to benefit even the poorest, and at the same time to promote the providence and independence of the working classes? Is it possible to adopt a plan of work which, while meeting the above requirements, will render the movement self-supporting?

Unhappily, as usually managed, institutes of district nursing, instead of increasing the independence and self-reliance of the working classes, exert the opposite effect and encourage the poor to depend on the gratuitous help of the rich. In other words they tend to demoralise, instead of fostering a spirit of self-help and thrift. Moreover, the voluntary subscriptions given by the well-to-do in the neighbourhood are generally insufficient for the purpose, in consequence of which the utility of the work is curtailed and an inadequate staff of nurses endeavours to cope with an overwhelming amount of sickness. Even when the sick poor are encouraged to contribute towards the maintenance of the nurse (e.g. a few pence per visit), experience proves that it is almost impossible for them to do so, when illness comes and swallows up every penny of the weekly earnings.

These difficulties and objections will vanish if district nursing is organised on a provident self-supporting basis—on such a basis as is adopted by provident dispensaries and medical clubs. The latter supply medical attendance and medicines on condition that a small annual payment be made in advance, and the supply of skilled nursing may be organised on the same principle. Of course, the annual subscription must be on a most modest scale, and in proportion to the means of those to be benefited. For the sake of argument the sum may be stated at 1*s.* per annum per individual, but this, like other details, may be modified to suit local requirements. The sum of 1*s.* is equivalent to about a quarter of the amount usually paid annually for the dispensary or club medical man, and is probably as much as can

Digitized by Google

be collected from a member of the wage-earning class. Moreover, it is adequate for the purpose of making district nursing self-supporting, as will be shown hereafter. In the case of a family, 2*s.* 6*d.* per annum would probably be a sufficient charge, as the mother can, as a rule, do what nursing is required for the children, and only rarely will need more skilled assistance. When feasible, the collection of the annual contributions may be undertaken by the machinery of the local dispensary or benefit societies, which will, after deducting the cost of collecting, hand over the balance to the District Nursing Association, and in return have their members enrolled on the register of that Association. Another plan would be to include the services of the district nurse amongst the benefits a provident dispensary offers to its members, a small capitation charge being levied for the purpose. The total sum contributed towards the expenses of the nursing association per 1000 persons would vary somewhat, according to the relative proportion of unmarried persons and families, and according to the amount charged to each. But, on the basis suggested above, approximately £25 per annum would be collected. Thus 4000 members would yield £100 towards the expenses of the district nurses, and so on in like ratio. The annual cost of a trained district nurse is roughly estimated at from £80 to £100 a year, so that 4000 members would in the aggregate contribute a sufficient sum for her support. In addition, experience proves that one district nurse is amply sufficient for 4000 persons. Indeed, in many towns with a large artisan population, one nurse suffices for a population of 6000 or 8000. Hence it follows that upon this provident basis district nursing may readily be made self-supporting. In order to encourage payment in advance of the annual subscription, it would probably be desirable to exact an extra fee of perhaps 5*s.* from any person who had neglected to make himself "free of the nurse," and yet desired her services when sickness came.

One objection to this scheme may be raised—viz., that in some homes there is such extreme poverty that even 1*s.* a year cannot be paid, and yet the visits of the district nurse may be eminently required. This difficulty, which only applies to exceptional cases, may be met, if thought desirable, by adopting such a plan as that in vogue at some provident dispensaries, where subscribers, in return for their contributions, are entitled to free nomination tickets to be reserved for cases of extreme poverty. The recipient of such a ticket would be entitled to the gratuitous services of the nurse. Probably for an annual subscription of £1 about four such tickets might be given. Where there is actual destitution, the guardians of the poor have power, under an order of the Local Government Board dated Jan 27th, 1892, to apply the rates for the purpose of nursing the out-door paupers, as is already done in the case of over 100 unions in various parts of the country. Such a course obviously tends in the long run to keep down the rates by diminishing the number of sick who would be compelled to go to the workhouse infirmary and also by helping to restore to health those who are dependent upon out-door relief. It is probable, therefore, that the guardians of the poor will frequently avail themselves of the occasional services of the district nurse and subscribe to her support.

The question may perhaps be asked, What need is there for the capital fund that is being raised in various localities towards establishing an institute of district nursing, if this can be worked on a provident, self-supporting basis? The reply is that such a fund, although not absolutely necessary, will help to give the movement a good start, by acquiring and furnishing a home for the nurses without deducting anything for the purpose from the contributions of the provident members. Moreover, there are various sick appliances, such as air-cushions, feeders, clinical thermometers, &c., which should be provided, and which can be lent gratis to provident members when the need arises.

In dealing with rural districts and a scattered population, some modification of the details of this scheme will be required, in adaptation to local circumstances. If on the one hand, the distances to be traversed by the nurse are greater and the number of visits she can pay is consequently reduced, this, on the other hand, will be to some extent compensated for by the more healthy condition of our rural population, which will less often require her services. But even if the details are altered, it is equally important to maintain a provident basis of work as preferable from its moral and economic aspects to a charitable one. The above remarks have referred especially to localities in which district nursing is being established in commemoration of Her Majesty's sixty years' reign. But there can be no great difficulty in introducing this scheme, even where the basis of work has hitherto been a charitable one. The two methods may for a time be worked side by side until the provident system is gradually substituted for the less desirable one.

In conclusion, this method of organisation presents several distinct advantages. First, the institute of district nursing, when once started, will be independent of charity, and can be maintained on a self-supporting, and therefore healthy, basis. Secondly, the working classes, instead of being encouraged to depend on the gratuitous help of others, are encouraged to make provision against the day of sickness, and a habit of thrift is promoted. Thirdly, the services of the district nurses will be more appreciated than if rendered gratuitously. Experience teaches that people value most what they pay for, and assuredly this applies to the question under discussion. The cumulative weight of these arguments must be readily apparent. No laments will be heard that the funds are insufficient for the work, and that an inadequate staff of nurses vainly endeavours to cope with an overwhelming amount of sickness. The institution becomes a help-myself nursing organisation, and enables the poor, by voluntary combination and at a trifling cost, to provide for skilled nursing, just as, by means of a provident dispensary, they now provide for medical aid and medicine. Such an institution, established on a provident, self-supporting basis, will be a power for good in a district, and will minister to the social welfare of the working classes.

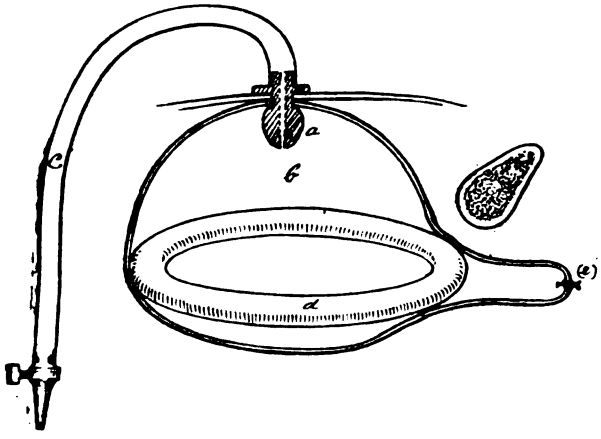
ANOTHER METHOD OF AMELIORATING BY OPERATION OTHERWISE INCURABLE INCONTINENCE OF URINE.



BY WM. ALEXANDER, M.D.R.U.I., F.R.C.S.ENG.,
SURGEON TO THE ROYAL SOUTHERN AND WORKHOUSE HOSPITALS, LIVERPOOL.

IN the fourth volume of the *British Gynæcological Journal*, p. 215, an uncorrected paper of mine appears, entitled "A Method of Treating Incontinence of Urine in the Female in Cases hitherto considered to be Beyond the Resources of Surgery." In that paper a fair amount of success was obtained by turning a paralysed urethra into the rectum, the latter viscus being able to retain the urine so long as to make the patient comfortable. This patient died about twelve months after operation, but not before she had put beyond doubt the practical use of this method of relief. Her condition was much inferior to that of nature, as she was practically in a condition resembling diarrhœa, having from six to eight evacuations daily, but at the same time the condition was a great improvement on her previous state, where she was continually wet and "reeking" with a urinous odour. In the same paper another case is described where an attempt was made to relieve a patient whose urethra had sloughed away. The same principle was adopted of depending on the rectal sphincter, but although we were on the verge of success the patient left the hospital before the urethral opening was closed.

Two years ago, on April 30th, 1895, a woman, aged thirty-four years, came into the Royal Southern Hospital suffering from incontinence of urine that had existed for the past fourteen years. She had always been delicate (tuberculous), and fourteen years ago she had diseased bone removed from the sacrum. It was after this operation that her urinary troubles began. At first she could not pass urine, then it began to dribble away, and she could not retain it for any length of time, and soon it flowed away constantly except when she was asleep, and then she would keep fairly dry for short periods. Examination on admission showed that she had no control over the rectum or urethra, the sphincters were quite flaccid, and the mucous membrane everted and congested. The uterus dropped down, and the lower part of the vaginal walls was everted. The whole vulva and perineum were congested, excoriated, and covered with salts and mucus that adhered to the hairs and skin, and the whole region looked, smelt, and felt very unpleasant. The idea of

Digitized by Google

diverting the urine from the imperfect vesical reservoir into a rectal one, as had been done in the previous cases, was not applicable here, as the rectal sphincter was, in this case, paralysed, and would not hold water. I could find no reference to such a case in the manuals of surgery or in monographs on urinary diseases, and it was only after much thought that I determined to close the urethral opening, and make a permanent suprapubic opening as high as possible and to which an appliance could be fixed that would carry off the urine. How this idea was successfully carried out I will now proceed to show. The formation of a suprapubic opening did not present any difficulties, as the bladder could be pushed up into the wound by the aid of a catheter. The bladder wall was stitched to the wound in the skin, and the wound allowed to heal before the urethra was closed. The closure of the urethra is apparently a simple operation, but in practice I found it very difficult. Suprapubic drainage is very imperfect. The tube in the bladder becomes surrounded by mucous membrane and is practically closed, whilst the urine issues by the side of the tube, and, worst of all, the forces of nature tend to send the stream by the old channel, the urethra. Hence union of the plastic wound to close the urethra is not always or often sound along the whole line of suture the first time, and several operations were required in this case before closure was complete Experience suggests the following directions to the operator who wishes to close the urethra: First, insert a thin elastic ring pessary into the bladder through the suprapubic opening, which, when it expands, is to lie in the fundus vesicæ, with part of its circumference over the inner orifice of the urethra. This ring keeps the bladder from contracting, converts it into a pool that can be drained by a syphon, stops the natural tendency that exists to force the urine into the urethra, and blocks that opening. This extraordinary procedure was of great value, and I would certainly adopt it again. Its insertion, retention, and removal did not present any difficulties or inconveniences, although, theoretically, it should have produced both. The urethra is best closed by splitting the mucous and muscular coats, turning the former in towards the bladder, and stitching together its raw and now external surfaces with numerous fine catgut sutures. The raw surfaces of the muscular coat are simply brought together by fine silkworm gut sutures. The method of drainage is simplicity itself. It consists in the ivory nozzle of a Higginson's syringe with the curves of the neck and

The diagram represents the ivory nozzle (*a*) in the bladder (*b*), with its tube and stopcock (*c*), the pessary (*d*) lying in position in the bladder during the closure of the urethra, and the method of closure of the urethra (*e*).

body of the nozzle exaggerated so as to have the shoulder below the neck more pronounced. A rubber tube with a tap at the end that can be brought through the dress and so allow the bladder to be empted with more than usual facility completes the apparatus. It is really self retaining, but a bandage round the body prevents the ejection of the tube under any great strain or awkward twist of the body. When the tap is closed the urine collecting distends the bladder and the tube, and as these become distended the internal hydraulic pressure keeps the shoulder of the nozzle applied to the inner margin of the opening until the patient feels the distension and lets the water flow away. Dr. J. A. Craig and I were planning all sorts of apparatus to fit the aperture and keep the patient dry, but we found that the Higginson's nozzle was more effectual than all our perfect theoretical notions, and it took us some time to realise theoretically how such a simple contrivance was effectual. The patient left the hospital on Aug. 8th, 1896. She came to show herself on March 17th, 1897, with the apparatus in good working order, her skin quite dry, and healthy, no urinary odour about her, and her linen clean and unstained. She can manage quite well, no urine escaping except a little sometimes at night when she is asleep. Her uterus is protruding, and we have recommended an advancement of the perineum to support it, but as far as the incontinence is concerned the results have exceeded all our expectations. It supersedes completely the rectal reservoir idea, and does not come far short of affording all the advantages of the natural condition.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON THE INJURIES IN THREE CASES OF PERSONS STRUCK BY LIGHTNING.

BY E. POCKLINGTON, M.R.C.S. ENG., L.S.A.,
AND
R. T. POOLE COLLYNS, M.R.C.S. ENG.

As cases of injury from lightning are comparatively rare in this country the following may be of interest, having recently occurred in our practice.

On June 24th, at about 6 P.M. we were informed that one man and two boys had been injured on Wimbledon Common. The boys were aged respectively nine and eleven years, and had taken refuge from the storm in a temporary wooden structure without a roof, but they had apparently taken a sheet of galvanised iron, and propped it up on the wood as a shelter. When seen they were cold and collapsed, with a slow pulse, and seemed dazed; hearing was much impaired, but the eyesight was not affected; the elder one had a patch of hair, 1 in. by 3 in., over the left parietal bone singed and a red bruise on the left forearm; he complained of shooting pains in both wrists, the right being the worse. During the night both of the patients were violently sick, but in the morning they seemed but little the worse for the accident, except that they were slightly deaf. On examining the clothes after they were dry a dark round patch, the size of a shilling, was seen on the cap of the elder one, and two singed lines on the inner side of the left shirt sleeve.

The man was aged nineteen years, and was quite dead when found. A necropsy was made twenty-one hours after death. The body was well nourished. Rigor mortis was just commencing. The hair over the left parietal bone and on the left half of the body and the left leg was singed; there was a burn over the left clavicle where the brace buckle had rested, and there were also small round burns corresponding to the eyelet holes of the boot on the dorsum of the left foot. Arborescent lines were present over the whole of the body, being most marked on the left side of the chest and on the left thigh. On removing the skull cap a minute fissure which corresponded with the singed patch of hair was found; the vessels of the dura mater were gorged and the left ventricle of the brain contained much fluid, while the right contained only a normal quantity; the blood throughout the body was fluid and there was only one small clot on the left side of the heart; all the organs were much congested. On examining the clothes a small hole was found in the cap and the inside lining was much torn. The left sock was in rags and the left boot was burst open along the outer side. The sole was intact; the nails round the sole were brass, but there had evidently been three large steel nails as in the usual place for these there were holes with charred edges.

A NOTE ON TWO UNUSUAL COMPLICATIONS OF MIDWIFERY.

BY J. B. PIKE, M.R.C.S. ENG.

ON Oct. 2nd, 1896, I attended a multiparous woman. On arriving I found a tumour protruding from the anterior part of the vagina. It was somewhat difficult to ascertain its nature. In consistence it was something like dough, covered by mucous membrane, but with an indistinct feeling of fluctuation. It was almost plum-coloured, and about 2 in. long by 1 in. broad. Emptying the bladder had no effect upon it, and on making a complete examination it was found to be continuous with the os uteri. The head of the fœtus was lodged on the pubes of a somewhat narrow pelvis. I delivered with forceps under chloroform, and the elongated and œdematous anterior lip of the os, for it was this which formed the swelling, gradually receded without any serious symptoms.

On Jan. 15th, 1897, I attended a married woman. A midwife was in charge of the case, and her history of it was that it was something "she had never seen before." There was a contraction of the vaginal outlet so great that one finger could only be inserted with some force, and then only up to the middle joint. The woman had already borne a child with a natural labour. The contracted band, which was probably cicatricial, was divided by multiple incisions under chloroform, until sufficient room was gained to dilate with the hand, and the case was completed with forceps. Posteriorly a finger could be passed under the mucous membrane, between the vagina and the rectum, but owing in great measure to the excellent nursing of our district nurse the case went on very favourably.

NOTE ON A CASE OF ACUTE ASCENDING PARALYSIS.

BY E. CECIL WILLIAMS, M.B. CANTAB.,
PHYSICIAN IN CHARGE OF OUT-PATIENTS, HOSPITAL FOR SICK CHILDREN AND WOMEN, BRISTOL.

THE probable diagnosis of the following case rests almost entirely on the history given by the mother, as the child was seen only twice just before death. The mother refused to allow the child to be admitted into the hospital, and it was impossible to obtain permission for a post-mortem examination. There had been seven children, the fifth and sixth of whom had died at ten weeks. The mother said that both had appeared perfectly healthy at birth. At the end of the first week she noticed that they did not kick when they had their baths, they gradually got weaker, the paralyses extending upwards, and both died at ten weeks, with inability to swallow or cry and failure of respiration—symptoms of bulbar paralysis. The elder children were perfectly healthy. The youngest, a full-time male child, appeared at birth to be quite healthy. At the end of the first week the mother noticed that the child did not use his legs. She said that he gradually got more feeble, but not so rapidly as the two previous children had done. At six weeks the mother noticed the breathing to be peculiar. When I first saw the child two weeks before his death he was in the following condition. The arms were slightly flexed, the forearm and hand were in a position of hyperpronation. It was impossible to fully extend the forearm on the arm; the tendon of the biceps could be felt perfectly tense when an attempt was made to extend the forearm. It was also impossible to fully supinate the hand and forearm; the fingers were slightly flexed into the palm. The intercostals were paralysed; there was diaphragmatic breathing. The abdominal muscles did not move. The legs and feet lay motionless and perfectly helpless; there were no contractures of the feet. The knee-jerks were abolished, and the plantar reflexes were almost absent. There was no muscular wasting, and sensibility did not seem to be impaired. The child did not have any difficulty in passing urine or motions; the latter were very offensive. He rapidly became worse, was unable to swallow, there was difficulty of respiration and inability to cry, and he died aged four months and two weeks. From the mother's account, which I have every reason to believe is a correct one, there seems to be no doubt that it was an ascending paralysis. There had not been any difficulty at birth; the labour was natural. There was no history of syphilis; the mother was perfectly healthy. She never noticed any sore on the cord that could have been the means of entry of any poison. There did not appear to be any swelling of the spleen or any of the mesenteric glands. They lived in a perfectly healthy house in the country; there was no history of malaria.

Landry's paralysis has occurred very rarely in children.[1] A case has been recorded in a boy aged eleven years, but it may possibly have been a case of peripheral neuritis; the boy recovered.[2] A case of ascending paralysis after whooping-cough has been recorded in a boy aged three years. The case recovered. It was regarded as of toxic origin.[3] Landry's paralysis is now regarded as being caused by a toxin. The occurrence of the disease in three successive children, commencing in the same way and running an almost identical course would in this case seem to suggest a common cause, possibly of toxic origin. The progress of this case was perhaps somewhat slow, but the symptoms fit in extremely well with those of Landry's paralysis, as given by Diller and Meyer.[4]

Clifton, Bristol.

NOTES OF TWO CASES OF DERMATITIS FROM CONTACT WITH THE PLANT "ANGELICA."

BY DAVID WALSH, M.D. EDIN.,
PHYSICIAN TO THE WESTERN SKIN HOSPITAL, LONDON.

THE dermatitis venenata set up by contact of the skin with various drugs and plants is interesting from various points of view. In this country perhaps the most common form in recent years is that due to the "primula obconica." A short while since two cases of acute dermatitis caused by gathering the plant "angelica" came under my notice.

A youth, aged eighteen years, a confectioner, pale, but apparently well-nourished, presented himself at the Western Skin Hospital on May 24th, complaining of an irritating rash on the forearms. He himself attributed the attack to the gathering of the plant "angelica," which he called "cow's parsley," in Regent's Park six days previously. When cutting the plant he had his sleeves rolled up and the leaves and juices came freely into contact with the front of the forearms. Next day he was attacked with an intensely burning and itching pain. On examination the parts indicated were found to be in an acutely inflamed condition and the inflammation was rapidly spreading both round to the back of the forearms and down to the hands. On the right forearm was a broken bleb the size of a shilling. The patient stated that a friend who helped him in gathering the plant was attacked in a similar fashion. In the friend's case, however, there was much more blistering and less pain, and the patient recovered in a few days under treatment with a simple zinc ointment. This rapid cure is interesting when compared with the intensity of the process in the patient who came to the hospital, and in whom the dermatitis persisted for several weeks.[5]

I have been unable to find any record of similar cases, although the plant, or rather its resin, is mentioned by Fernie as a skin stimulant. In the present case it was gathered for the purposes of preserving. When candied it is used very largely by confectioners for ornamenting cakes, and is not unlike fine green stalks of celery in appearance. In his book on "Herbal Simples" Fernie gives the following account of "angelica" (or "master-wort"): "The wild Angelica grows commonly throughout England as an umbelliferous plant, with a tall, hollow stem, out of which boys like to make pipes. It is purple, furrowed, and downy, bearing white flowers tinged with pink. But the herb is not useful as a simple until cultivated in our gardens, the larger variety being chosen for this purpose, and bearing the name Archangelica. It came to this country from northern latitudes in 1568. The aromatic stems are grown abundantly near London in moist fields for the use of confectioners. These stems when candied are sold as a favourite sweetmeat; they are grateful to the feeble stomach and will relieve flatulence promptly. The roots of the garden Angelica

Digitized by Google

contain plentifully a peculiar resin called "angelicin," which is stimulating to the lungs and to the skin. The infusion will relieve flatulent stomach-ache and will promote menstruation; it is also of use as a stimulating bronchial tonic in the catarrh of aged and feeble persons. Angelica is said to cause a disgust for spirituous liquors. In high Dutch it is named the root of the Holy Ghost. The fruit is employed for flavouring some cordials, notably Chartreuse. Gerard says: 'If you do but take a piece of the root and hold it in your mouth; chew the same between your teeth; it doth most certainly drive away pestilent aire.'"

ROYAL FREE HOSPITAL.

A CASE OF CONGENITAL SHORTNESS OF METACARPAL AND METATARSAL BONES.

(Under the care of Mr. E. W. ROUGHTON.)

A DOMESTIC servant, aged thirty years, applied for treatment on account of an inflamed corn on the third toe of the left foot. It was noticed that the fourth toe was much shortened. The right foot at first sight appeared normal, but on closer examination it was seen that the big toe was shortened owing to the metatarso-phalangeal joint being

further back than usual. The hands presented a similar deformity. When the fingers were extended the tips of them were very nearly in line owing to relative shortness of the middle and ring fingers. When the fingers were flexed at the metarcarpo-phalangeal joint the knuckles presented an irregular line owing to shortness of two of the metacarpal bones. The accompanying skiagraph demonstrates very clearly the nature of the malformation. The fourth metatarsal bone of the left foot, the first metatarsal bone of the right foot, and the three inner metacarpal bones of both hands are stunted, being about two-thirds of their normal length. The heads of the bones are curiously mis-shapen, somewhat resembling the changes met with in large joints affected with Charcot's disease. The patient presented no other deformity and knew of no similar condition in any other member of her family. She complained that her hands were somewhat weak, but her feet caused her no trouble with the exception of the inflamed corn, which was due to an ill-fitting boot.

Remarks by Mr. ROUGHTON.—The patient attributed the deformity of the hands to an injury she had received in childhood, but she could offer no explanation of the condition of the feet. I think there can be no doubt that the deformity is of congenital origin, but I am unable to offer any further explanation of it.

BRISTOL GENERAL HOSPITAL.

A CASE OF MULTIPLE ANEURYSM; NECROPSY; REMARKS.

(Under the care of Dr. J. LACY FIRTH.)

A MAN, aged sixty-eight years, was in September, 1896, admitted to the Bristol General Hospital under the care of Dr. J. Lacy Firth. The patient complained of a cough which he had had for twenty years, of weakness, of some difficulty in swallowing, and of pain and numbness in the arms and fore-arms. He first noticed pain in the arms, chiefly in the axillæ, fifteen months previously. The pain led him to examine the axillæ and he found a swelling in each. He ceased to work twelve months previously. The swelling in the right axilla, he said, had diminished latterly, and the severe pain, which used to shoot down the arm and fore-arm had also diminished. In fact, on admission he said he considered that there was very little amiss with the right arm. No history of syphilis or other venereal disease was obtainable. He had worked as an ordinary labourer all his life since boyhood, with the exception of a year or two at first, when he had acted as stoker on a steamer. He was thin, sallow, and broken-down in appearance, with a weak and hoarse voice. His cough was very troublesome, and examination of the chest revealed signs of bronchitis and emphysema. There was deficient expansion of the chest and prominence of the sterno-mastoids in the neck. Numerous râles were audible over the lungs and the cardiac dulness was replaced by resonance. Careful inspection revealed a slight degree of pulsation in the second right intercostal space close to the sternum, and the first, second, and third spaces on this, the right side, had impaired percussion resonance near the sternum. Occasionally, and only with difficulty, a faint systolic bruit could be heard in the same area. The apex beat was in the fifth left space and half an inch internal to the nipple line and was feeble and the heart sounds were weak. No cardiac bruits were heard. Beneath the right sterno-mastoid with the fingers and thumb passed deeply behind its internal and external borders respectively, the carotid artery could be grasped and was felt to be dilated into a fusiform swelling, extending two and a half inches upwards from the clavicle. With the arms abducted there was seen protruding downwards between the axillary folds on each side a globular swelling with expansile pulsation. Palpation showed these to be the lower extremities of oval pulsating tumours extending upwards in the axillæ towards the clavicles, and the upper ends could not be reached from below. The left one was a good deal larger than the right, and produced conspicuous bulging in the sub-clavicular region. The cephalic veins in both arms were distended and there was a network of distended veins in the right sub-clavicular region. The right radial pulse was weaker and smaller than the left. The patient died from bronchitis and exhaustion a few weeks after admission.

Necropsy.—The heart, thoracic aorta, and branches of the arch, the axillary arteries and portions of the brachials were removed *en masse*, with the trachea and œsophagus. There were found an aneurysm of the second and third parts of each axillary artery of the mixed fusiform and saccular type, a fusiform aneurysm of the right carotid, a mixed aneurysm of the innominate artery, and dilation of the ascending aorta. Of these the innominate was the largest. It involved the whole of the artery and was four inches long

Digitized by Google

and two and a quarter inches in diameter. The right subclavian and carotid arteries sprang from the convex upper surface of the aneurysm and were a third of an inch apart at their origins. The axillary aneurysms were closely surrounded by the branches of the brachial plexus of nerves. The left was four inches long, and the right two and a half inches. The carotid aneurysm was two inches long and purely fusiform. The right bronchus was concealed behind the innominate aneurysm. There were no valvular heart lesions or conspicuous renal changes.

Remarks by Dr. FIRTH.—Aneurysms are usually single. It is not, however, uncommon to meet with symmetrical aneurysms of each popliteal artery. The similarity of the anatomical relations of the two arteries and the equal functional activity of the affected parts render each of these arteries equally liable to form an aneurysm. But symmetrical aneurysm of each axillary or subclavian artery is rare. In these arteries aneurysm is almost always single, and much commoner on the right side than on the left, no doubt by reason of the greater functional activity usually of the right arm. For the same reason one would expect a right aneurysm of the axillary artery to be larger than the left in a case of double aneurysm, but in my case the right was the smaller. Probably the diminution in size of the right aneurysm and the amelioration of the pressure symptoms were due to the development of the innominate aneurysm, and the weaker pulse on the right side, the side of the smaller axillary aneurysm, is similarly explainable. Erichsen[1] stated that he was acquainted with only one case in which both axillaries were aneurysmal. The same writer mentions two cases in which symmetrical intracranial aneurysms formed on the internal carotid arteries, and Mr. Pearce Gould[2] has alluded to examples of aneurysm in each vertebral artery within the skull, and even of one in each hepatic artery. Identity of anatomical relationship will again explain the symmetry of these aneurysms. Multiple aneurysms are sometimes developed in patients with rheumatism and malignant endocarditis, and are of embolic origin. Spontaneous aneurysm in young people under twenty years of age is probably always embolic and found in association with valvular heart disease, and is frequently multiple. A special aneurysmal diathesis is sometimes spoken of as explaining the existence of multiple aneurysm. But there is no advantage gained by using such an expression. Multiple aneurysms obviously form, because the degeneration of the arterial walls has advanced sufficiently far, in more than one place, to yield before the blood pressure. As degeneration of arteries is a widespread change, it is remarkable that multiple aneurysm is not more frequently met with. Perhaps the infrequency of its occurrence points to the frequent operation of other accessory and immediately exciting causes in the production of the aneurysm, in addition to the predisposing cause of arterial degeneration—e.g., of injury, which ruptures an atheromatous abscess in the middle, or middle and internal coats of the artery. Erichsen mentions an extraordinary case of Pelletan's, in which there were no less than sixty-five aneurysms present.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

A CASE OF LARGE PAROTID TUMOUR SUCCESSFULLY REMOVED FROM AN OLD MAN.

(Under the care of Mr. FREDERICK PAGE.)

THE complex new-growth of the parotid gland, which is often called the "glandular parotid tumour," is on the whole possessed of but little malignancy; in most cases these growths are readily removed after having existed for years and having attained a large size.[1] Their structure has claimed for them the cacophonous title of chondro-myxo-fibro-adenoma, for they frequently contain all these tissues. The

malignancy which they sometimes possess is apparently dependent on the presence of sarcomatous elements amongst the fibrous tissue.

Some eight years ago Mr. Page was consulted by a man with a large parotid tumour of many years' growth and recommended its removal. The patient refused to undergo an operation on account of his age. In July, 1896, Mr. Page again saw the man, who was then seventy-one years old. The tumour had grown a good deal, protruding into the

[1] Paget: Lectures on Surgical Pathology of Tumours, third edition, p. 521.

Digitized by Google

mouth and throat so as to seriously interfere with his swallowing and his breathing. The illustration shows very well the condition. An operation had become necessary. On Aug. 1st a long incision was made through the skin from the right ear nearly to the angle of the left jaw, and the tumour was enucleated in one mass without injury to the mucous membrane of the mouth and throat. The growth was somewhat firmly connected with the base of the skull, and it was necessary to plug the upper part of the deep wound in order to check bleeding from a vein which could not be tied. Very little constitutional disturbance followed, and the patient made a rapid recovery. In consequence of injury to the facial nerve the cornea of the right eye sloughed, and the eye was removed in the following October. The patient was in good health till a week ago, when he died at the age of seventy-two years.

Remarks by Mr. PAGE.—The case illustrates the uncertainty as to the difficulty in removing these large chronic parotid tumours. Great difficulty was anticipated in this case, but the tumour shelled out quite readily, and very little blood was lost. The old man, too, bore the operation well.

FYZABAD SADR DISPENSARY.

A CASE OF CIRSOID ANEURYSM OF THE SCALP; LIGATURE AND ACUPRESSURE FOLLOWED BY IMMEDIATE AND COMPLETE EXCISION; RECOVERY.

(Under the care of Surgeon-Major J. J. PRATT, I.M.S., Civil Surgeon, Fyzabad.)

CIRSOID aneurysm is a comparatively rare condition, and its treatment presents great difficulties to the surgeon. Should the incision invade the diseased tissue the hæmorrhage is so profuse as to endanger the life of the patient, and, further, the thinning of the arterial walls often extends much beyond the apparent swelling, so that the disease is very liable to return and progress after the original mass has been destroyed or removed. The procedure adopted by Surgeon-Major Pratt promises well to be the best method of treatment, as the preliminary ligature of the supplying arteries prevents any great danger of hæmorrhage during the operation, and the complete excision of the diseased vessels offers the best guarantee against recurrence. Mere ligature of the arteries entering the tumour is of very little benefit. It would be of interest to learn the condition of the patient when a longer period has elapsed since the operation.

A Brahman, aged thirty years, was admitted into the dispensary on Jan. 4th, 1897, suffering from a typical cirsoid aneurysm of the left side of the scalp. The arteries affected were the temporal, both anterior and posterior branches, and the occipital. The tumour, which was prominent and lobulated on the surface, occupied practically the whole of the left side of the head above and behind the ear, and was made up of a number of dilated and tortuous arterial branches, the largest of which in their most dilated parts were equal in size to an average forefinger. Pulsation could not be entirely checked by compression of the temporal in front of the ear and the occipital immediately above the nape of the neck, where in its enlarged condition it first became visible. It was consequently evident that to some extent, as was to be expected, the tumour was fed by the supra-orbital and frontal arteries of the same side and the temporal artery of the opposite side, and, as a matter of fact, on careful examination these were found to be slightly enlarged. A thrill was detected over the centre of the growth and for some distance along the larger feeding vessels. The patient stated that three years ago he noticed a small, rounded swelling on the left side of the top of his head, which pulsated and was painful. It slowly but steadily increased in size until it attained its present dimensions. Four months ago he lost a considerable quantity of blood from it and nearly died. Fearing a recurrence of this mishap he sought surgical aid in the hope of a cure being effected. He was unable to assign any cause for the growth, and could not recollect having sustained any local injury prior to its first appearance. The skin over the most prominent part of the tumour in the posterior parietal region was atrophied and thinned to a dangerous extent and in one spot showed signs of having given way not long before, thus bearing out the truth of the patient's statement regarding the hæmorrhage which had occurred. The case was manifestly one in which immediate operative interference was called for. Accordingly, on the morning of Jan. 7th, the patient, who was in fair condition but decidedly anæmic, was placed under the influence of chloroform, the scalp having first been carefully shaved and cleansed. An incision was made over the left temporal artery immediately in front of the tragus and the vessel at once ligatured. At the other end of the tumour a harelip pin was passed underneath the occipital artery and a ligature tightly applied round it. The pulsation in the tumour was then found to have almost entirely stopped; in one or two places only was it faintly perceptible. An incision was then made gradually around the whole mass of the tumour, commencing at its posterior border about an inch above the spot where the needle was passed under the occipital artery. Forcipressure was applied in fourteen places in the course of the incision. The tumour was then dissected off the pericranium, ligatures of carbolised catgut were applied round the different bleeding points, and the forceps removed. Three vessels in the pericranium which could not be tied gave considerable trouble; finally, the bleeding from them was arrested in two by acupressure and in the third by the application of a pair of bulldog forceps, both needles and forceps being left for the time being *in situ*. The edges of the wound, which measured five and a half inches in length by a maximum of three and three-quarter inches in breadth, were then brought together as far as possible by harelip pins and sutures, its surface was swabbed with a solution of perchloride of iron and a compress and bandage were firmly applied. The loss of blood during the operation was considerable, but, taking the nature of the case into consideration, no more than was to be expected. The patient was kept in absolute quiet and rest and on liquid diet. A mixture containing small quantities of quinine and opium was administered with a view to checking the rise of temperature so common in malarial subjects after surgical operations of any kind. The progress of the case was as follows. On the 7th, 8th, and 9th he was doing well. There was no pain or hæmorrhage. The dressings were left undisturbed. On the 10th the compress and bandage were removed. The surface of the wound in the scalp was covered with iron scab. It was dressed with iodoform and carbolised lint. The incision over the temporal artery had practically healed. The morning temperature was normal, the evening temperature being 100° F. A saline diaphoretic and laxative mixture was ordered to be given every four hours. On the 11th there was no fever and he was doing well. On the 14th the temperature was normal. Two harelip pins and several sutures were removed. On the 15th the margins of the wound were granulating. The acupressure needle from beneath the occipital artery and the remaining stitches were removed. On the 17th the progress was maintained. The patient was on full diet and was putting on flesh. On the 19th the ligature on the temporal artery came away; the wound was contracting. On the 26th progress had been uninterrupted during the past week. By Feb. 6th the wound had become considerably reduced in size and was rapidly healing. There was no pulsation in any vessel in the neighbourhood. The arteries of the front and the opposite side of the scalp had returned to their normal size. On the 22nd the patient was discharged to the out-patient department with a healthy granulating ulcer of the scalp two and a quarter inches long by one and three-quarter inches broad at the widest part.

HOSPITAL REFORM AT BRISTOL.—A meeting of the Hospital Reform Association was held at Bristol on June 16th under the presidency of Dr. Markham E. Skerritt. The discussion which took place brought out the fact that while the medical profession at Bristol are agreed that reform of some sort is necessary, they are not quite unanimous as to the direction in which reform should go. The following resolution, proposed by Mr. Garrett Horder, was passed: "That in the opinion of this meeting it is most desirable that the medical charities of Bristol and Clifton should be restricted as far as possible to the wants of the necessitous poor, and it is further of opinion that the recommendations of the Hospital Reform Association for the prevention of the abuse of the out-patient and casualty departments are deserving of consideration by the governing bodies and acting medical staff of the various hospitals and dispensaries."

Medical Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Carcinoma of the Cervix treated by Curettage and Chloride of Zinc Paste.—Puerperal Peritonitis treated with Anti-streptococcic Serum.—Exhibition of Specimens.

A MEETING of this society was held on June 10th, Mr. A. W. MAYO ROBSON, the President, being in the chair.

The Secretary read a paper by Dr. JOHN MEEK (Canada) on two cases of Advanced Carcinoma of the Cervix treated by Curettage and Chloride of Zinc Paste. The first patient made a good recovery. In the second case the patient went on well for four days with no rise of temperature and passing plenty of urine; then suppression of urine supervened; the bladder was empty. There were no uræmic symptoms after the stoppage for forty-eight hours, then there was a tendency to stupor and occasional slight delirium for twenty-four hours preceding death. There was no post-mortem examination, but it was probable that the ureters had become obstructed from pressure of the eschar, the result of the zinc cauterisation.—Mr. BOWREMAN JESSETT and Dr. PURCELL, speaking on the paper, said that they had now treated about fifty or sixty cases at the Cancer Hospital by this method with one death. There were about a dozen patients operated upon from one and a half to two and a half years ago who presented so far no recurrence. Though the treatment could not be considered curative it prolonged life and rendered it much more comfortable.

Dr. R. T. SMITH read a paper on a case of Puerperal Peritonitis treated with Anti-streptococcic Serum. The patient, a primipara, had been the subject of tubal mischief. The labour was normal, and so was the puerperium for two days, after which symptoms of septicæmia set in, and it was thought that this might be due to rupture of the diseased tube. The question of abdominal section was considered, but it was decided against. On the fifth day 10 c.c. of anti-streptococcic serum were injected, repeated on the seventh day. There was temporary improvement, after which the patient became worse, and on the ninth day abdominal section was again considered, but it was thought that the patient was too weak for it, so stimulants were pushed and the serum treatment persevered in. Alternations of improvement and relapse succeeded, but eventually the patient began to gain ground, and finally recovered. Dr. Smith concluded that abdominal section in the first instance would probably have been the wiser plan. The serum treatment certainly did no harm, and probably in this case prevented a fatal issue; he thought that it was well worth trying in such cases.—Dr. JOHN SHAW said that he had used the anti-streptococcic serum in one case. The puerperium was normal for three days, then fever developed. He at once began with 20 c.c. of the serum; in six hours another 10 c.c. were given, and this amount was then repeated twice daily. He noted that the temperature always seemed to be higher just after the injection. Streptococci were found in the vaginal secretion. Eventually an abscess formed in the left Fallopian tube.—Dr. GRANVILLE BANTOCK thought that there was no distinct evidence that the serum played any important part in the favourable result.

Dr. MACNAUGHTON JONES showed a specimen, together with a microscopical preparation, of Carcinoma of the Kidney for which nephrectomy was performed. The patient made a good recovery.—Mr. BLAND SUTTON said that the malignant tumours of the kidney were—(1) carcinoma, like the present specimen, which was extremely rare; (2) sarcoma arising in the connective tissue of the pelvis of the kidney; and (3) sarcoma associated with the suprarenal capsules, which was probably the least malignant form.

Mr. R. H. HODGSON showed a specimen of Fibro-myoma of the Right Broad Ligament. It was so closely associated with the uterus that he performed panhysterectomy. The patient made a good recovery.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

Election of Officers.—Climatic Treatment of Phthisis.—Gouty Liver and Sulphur Spas.

THE second general meeting of this society was held at the rooms of the Medical Society of London on June 9th, the President, Dr. ANDREW S. MYRTLE (Harrogate), being in the chair.

The officers for the ensuing year were elected, Dr. William V. Snow (Bournemouth) being the President-elect.—Dr. HYDE read the report of the Council. The total number of Fellows was now 340.

The adjourned discussion on Dr. SNOW'S paper dealing with the Climatic Treatment of Phthisis was resumed.—The following took part in the discussion: Dr. SYMES THOMPSON, Dr. WILLIAM EWART, Dr. CARL RUEDI, Dr. ROBERT LEE, Dr. ST. CLAIR THOMSON, and Dr. SEPTIMUS SUNDERLAND.—Dr. SNOW, in replying, said that he believed that treatment by altitude in suitable cases would secure more permanent and better results than by treatment in the South of France, England, or anywhere else. There were few cases he would send to South Africa other than young men whose friends could provide moderate means and who were likely to be satisfied with the open-air life on farm land.

The PRESIDENT then read a paper entitled Gouty Liver and Sulphur Spas, giving the results of his treatment of certain cases of enlarged liver occurring in gouty subjects by the use of the Harrogate sulphur waters. He never resorted to deep massage until the congestion and enlargement of the liver had been much relieved by the waters.

Reviews and Notices of Books.

Materia Medica, Therapeutics, and Pharmacology. By GEORGE FRANK BUTLER, M.D. Pp. 858. London: The Rebman Publishing Company. 1897. Price 22s. 6d.

THIS book is dedicated to the medical students of the United States, and the author is Professor of Materia Medica and Clinical Medicine in the College of Physicians and Surgeons, Chicago, hence for English readers it necessarily contains much that extends beyond the range of English practice in relation both to pharmacopœial drugs and pharmaceutical preparations. The author excuses the omission of reference to many new and comparatively untried remedies on the ground that they are as yet too imperfectly known to warrant association with remedial agents bearing the sanction of exhaustive scrutiny, but to balance matters, he has also excluded a few official drugs (U.S.P.), because they are practically never used or are employed only in isolated instances.

The arrangement of the material in this book differs considerably from that which is ordinarily adopted. The early pages comprise a classification of medicines and also the usual tables of weights and measures, and these are immediately followed by a detailed consideration of pharmaceutical preparations. In connexion with these the author aims at presenting in brief form the results rather than detailed descriptions of processes. A large number of elixirs are enumerated, and they are defined as being a class of "elegant preparations similar to wines or cordials, composed of water, sugar, alcohol, and aromatics." The list of elixirs extends over four pages, and they are obviously intended to act as vehicles to mask or modify the taste of nauseous drugs. The details given respecting these are scarcely sufficient to enable them to be dispensed, and the lists of these and of other official preparations indicate more the relative strength of the preparations than the exact constituents. Doubtless the author has exercised a wise discretion in thus eliminating mere technicalities of dispensing and preserving only those facts which it is important for the prescriber to remember.

The consideration of drugs employed in medicine naturally occupies the greater portion of the book, and drugs are for descriptive purposes considered under the headings of Disease Medicines, Antiseptics, Symptom Medicines, and Topical Remedies. It must be admitted that this classification

Digitized by Google

is extremely arbitrary. Thus, in the first class of Disease Medicines the author includes restoratives comprising digestants, fats and oils, mineral acids, vegetable acids, alkalies, mineral waters, bitters, and hæmatics; while under the heading of Symptom Medicines he groups together such remedies as antispasmodics, antipyretics, anæsthetics, hypnotics, and the like.

The general plan of the consideration of each drug is as follows. First, its origin is given with as few technicalities as possible, then the drug is described and its physical properties are dealt with briefly. The dose follows, and after this is placed a list of incompatibles, wherever it is possible for these to be enumerated; and having thus indicated with what remedies the particular drug cannot be given, the author next enumerates the synergists, or drugs which it is convenient to prescribe at the same time. These preliminaries are followed by a description of the physiological action, and this description necessarily varies in length according to the importance of the drug and according to the knowledge of the action upon the different physiological systems. With some drugs—as, for instance, with the compounds of arsenic—the physiological actions externally, locally, and internally upon the digestive system, circulatory system, nervous system, respiratory system, &c., are given in detail. The mention of this drug will serve to indicate one valuable innovation to be found in this work. After the physiological action, the author describes under a separate heading of Untoward Action the undesirable effects produced by medicinal doses in very susceptible persons. The description of these symptoms we greet with satisfaction, as they are in so many cases the indications for diminishing the dose, or for discontinuing the administration of the drug, and they are the symptoms which mark the border-line between beneficial and prejudicial actions of medicines, and should therefore be recognised before true toxic effects are to be expected. The paragraph upon Untoward Action is followed by a description of poisoning, both acute and chronic, together with a very brief account of the treatment of cases of poisoning.

Under the heading of Therapeutics the author describes the application of the drugs to particular diseases. In some cases he appends a short list of the contra-indications to the employment of the remedy, and also supplies sundry hints connected with the administration of the drug, these hints including such questions as the time of administration, the mode of administration with regard to dilution, and the reasons for selecting one official preparation rather than another.

After this detailed account of the various drugs employed in medicine, much space is devoted to the rules which govern prescribing in Latin. These rules extend to the language and grammatical construction of prescriptions, and some of the pages look very much like those of a Latin grammar, in which the names of drugs replace the old familiar variations of what Balbus did with a wall. It may be doubted whether in a work of this description it is necessary to give a half page to the declension of the numerals *unus*, *duo*, and *tres*. The author, however, defends the introduction of such very elementary facts by his concluding sentence, which runs thus:—"No matter how able a diagnostician, pathologist, or bacteriologist the new doctor may be, if his first effort in prescription writing be illegible, poor Latin, or for a hopelessly incompatible mixture, the druggist will label, classify, and measure him with the keenness of professional insight. The judgment will go forth quietly, and years of successful practice may not serve to eradicate that first unfavourable impression."

The information conveyed in this book is sufficiently up to date, and it is expressed in simple language under headings which facilitate reference and study.

Traité de Chirurgie clinique et opératoire. Par A. LE DENTU, Professeur de Clinique chirurgicale à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Necker, et PIERRE DELBET, Professeur agregé à la Faculté de Médecine de Paris. (*A Treatise on Clinical and Operative Surgery*). Tome I., pp. 822. Paris: J. B. Baillière et Fils. 1896. Price 12 francs.

THIS is the era of "Systems" of Surgery and the allied sciences. At the present time there are appearing five or six works, each devoted to surgery, and each consisting of several volumes, from four to as many as ten. Some claim to be "international," but most represent one country only. There are obvious advantages in having the various portions of a subject so large as surgery dealt with by several writers, for no one surgeon can represent adequately all its branches. Though the advantages are great, there are disadvantages no less certain and obvious. The great difficulty is that it is practically impossible to secure any real uniformity in the fulness with which the various departments of the subject are treated. It is the duty of the editor to attempt to reduce all the contributions to one uniform level and to remove any inconsistencies between the statements in different articles, but even when all possible care has been exercised it is never found that anything really resembling uniformity has been attained.

This treatise on clinical and operative surgery is intended to extend to ten volumes. With the names of Professor Le Dentu and Professor Delbet as editors we have a guarantee that the work will be well done. The distinguishing characteristic claimed for this treatise is that it contains an account of the surgery of the present day, not that of times which are past. Very little space is devoted to the history of the subject, and discarded methods of treatment are ignored. It is intended that it shall contain a full account of recent advances in pathological anatomy and in bacteriology, with all the important modifications which they have brought about in surgical therapeutics—those operative methods which have extended so much the field of surgical activity. This, the first volume, deals only with general pathology and the surgical diseases of the skin. The section devoted to general pathology is by several writers, and the most important article in it is that on Neoplasms by Professor Delbet, one of the editors. He gives an excellent account of the pathology of neoplasms, and treats with especial fulness the question of the etiology of malignant growths, which has of recent years received so much attention. After a very complete presentation of the views of all observers, with copious references to the work that they have done, Professor Delbet comes to the conclusion that, though it is possible that malignant tumours may be due to parasites, yet no satisfactory proof has up to the present time been given of any such origin. This is an opinion in which the majority of English pathologists will concur.

Cases have from time to time been observed, in which tumours, diagnosed as sarcomatous in nature, have either disappeared or undergone great diminution during an attack of erysipelas. These facts have naturally greatly impressed surgeons, and various attempts have been made to utilise the influence of erysipelas as a therapeutic agent in malignant disease. The first attempt was made by Fehleisen in 1882, and he was followed by many others, who employed the method both in sarcomata and in carcinomata, but in the former alone have the results been worthy of notice. Solutions of streptococci have been used in some cases, and in others sterilised and filtered cultures, and in others again streptococcic serum has been the agent employed. The results obtained differ greatly in the practice of different surgeons, but the conclusion to which Professor Delbet comes is that, though in most cases the injections have a

Digitized by Google

marked effect upon the growth, yet the effect is nearly always merely temporary, and in some cases death has resulted.

In the section on Cicatrices, by Dr. Lyot, an account is given of an operation of an exceedingly ingenious nature. Dr. Guermonprey (of Lille) had a patient in whom a large cicatrix, which had recently become sarcomatous, occupied the postero-lateral portion of the body and had commenced to invade the axilla. To cover in the large surface left after removal of the growth, the operator decided to sacrifice the upper arm while keeping the forearm and hand. The integuments of the upper arm, with some muscular substance, were raised in two flaps (anterior and posterior), with their bases at the shoulder, and were laid down on the bare surface resulting from the extirpation of the tumour. The shaft of the humerus was removed, and the two epiphyses were sutured together, the skin of the forearm being stitched to that of the shoulder. Unfortunately, we are not told what was the ultimate result of this heroic performance.

The surgical diseases of the skin are satisfactorily treated; but there are several other lesions of the skin which might have been considered surgical.

It is decidedly a pity that the volume has no alphabetical index; no doubt there will be an index in the final volume, but it adds much to the convenience of the reader if each volume in a treatise of many volumes has an index of its own. The illustrations are hardly satisfactory, they are scanty and crude. If the succeeding volumes equal the one before us, this treatise on Surgery will be excelled by none of those which have hitherto appeared.

Guy's Hospital Reports. Edited by E. C. PERRY, M.A., M.D., and W. H. A. JACOBSON, M.A., M.Ch. Vol. LII. London: J. & A. Churchill. 1896.

MANY besides "Guy's men" will read with sympathetic appreciation the tribute paid by Mr. Jacobson to Arthur Edward Durham. This memoir, to which is prefixed an admirable portrait, for fulness, for keen and loving analysis of a most lovable and gifted character, deserves a high place in biographical writings. It is surely inspired by no common affection, and it gives a picture of its subject which is worthy both of him and of his friend. Of the other contents of the volume we note three interesting contributions from the pen of Dr. F. Taylor, all of which are of considerable clinical interest. One is a record of a case of Shingles followed by Paralysis of Abdominal Muscles—a sequel so rare as to suggest the possibility of its being sometimes overlooked in an affection that is obviously neurotic in origin. Dr. Taylor also records some cases of Cirrhosis of the Liver in Children, in which he discusses the significance of the enlarged cirrhotic liver, its association with a greatly enlarged spleen, and the difficulties in the way of accepting any other satisfactory etiology than that of alcoholism. The subject is one of great interest, not only in regard to the dependence of cirrhosis upon alcoholism, but on the alleged distinction of biliary cirrhosis, and it is a question that can hardly be yet said to be solved. Dr. Taylor's third paper is on Splenic Anæmia, in which a case is recorded of marked splenic enlargement without leukæmia. The later stages of the case do, however, seem to show a decided increase in the white blood cells, whilst the decrease in the red corpuscles was very marked. In this case splenectomy was proposed, but was declined by the child's parents. Death occurred three months after leaving hospital, and no post-mortem examination was obtained. Mr. Davies-Colley writes a useful practical paper on Hallux Flexus, Claw Toe, and Pes Cavus, and Mr. Newland-Pedley one on Some Acquired Maxillary Defects and their Treatment. Dr. W. J. Tyson, in a paper on Cases of Appendicitis, distinguishes between the cases of simple perityphlitis (of which he thinks 2 or 3 per cent., or more, are due to fæcal accumulation in the cæcum), which recover under medical treatment, such cases forming the majority met with in practice; cases of perityphlitic abscess that demand surgical intervention; and those of acute general peritonitis, from necrosis of the appendix. There are notes of several cases in which operations were successfully had recourse to. Dr. C. R. A. Sutton writes on Albuminuric Retinitis, dealing with its pathology and its prognostic significance. He attributes the retinal changes to blood deterioration rather than to any uræmic condition, and points out that in acute nephritis and in early cases of pregnancy the retinitis often disappears with the albuminuria, and further gives reasons for believing that it is of far graver significance in chronic tubal than in interstitial nephritis. There are also papers by Dr. T. G. Stevens on Laceration of the Female Perinæum; by Dr. J. Fawcett on the Urinary Excretion in Gout, and the effect of treatment with colchicum and salicylate of soda; and by Mr. L. A. Dunn on a successful case of Pylorectomy for Carcinoma, in which Murphy's button was employed to unite the duodenum and stomach.

Reports from the Laboratory of the Royal College of Physicians of Edinburgh. Edited by J. BATTY TUKE, M.D. Edin., and H. NOEL PATON, M.D. Edin. Vol. VI. Edinburgh: W. F. Clay. 1897. 8vo, pp. 303, with eleven Full-page Illustrations. Price 8*s.* 6*d.* net.

THE present volume is stated in the preface to contain abstracts of longer papers which record the results of work done in the laboratory, but which have been published elsewhere, and also shorter communications which have been published in various journals. The old laboratory was founded in 1888, and consisted of an old house which was equipped at a cost of about £1000. It was situated close to the Royal Infirmary, and was immediately frequented by numerous workers, whose researches, represented by 114 papers, are contained in the five antecedent volumes of these reports. More space being urgently required, a new laboratory has been obtained, situated in Forrest-row and Bristo-street, and was occupied in June, 1896. The objects in view have been to provide a research laboratory for bacteriological, histological, chemical, physiological, and pathological work; to make provision for examining and reporting on specimens sent by medical men; to provide a photographic department for macro- and micro-photography; and to make suitable provision for carrying on the preparation of curative antitoxins. Several plates are given showing the ground plan and the interior of the laboratory, and the arrangements seem very convenient and complete. It is not practicable to mention all the articles contained in this volume, since there are no less than thirty-six. Many of them have appeared in other journals, but amongst the most important are, Observations on the Changes in the Mucous Membrane of the Corpus Uteri and in attached Fœtal Membranes during Pregnancy, by Dr. J. C. Webster, which was published *in extenso* in the *American Gynæcological and Obstetrical Journal* of New York. It is a valuable contribution to this subject, giving the characters of the decidua at different periods; and a Note on the Development of the Clitoris, Vagina and Hymen, by Dr. D. Berry Hart. The Anatomy of the Cæcum and of the Vermiform Appendix is given by Dr. Richard Berry, of Edinburgh. Dr. Noel Paton contributes articles on the Physiology of the Fats, on the Relationship of the Liver to Fats, and, in conjunction with Dr. G. Lovell Gulland, on the Absorption of Carbo-hydrates by the Intestinal Epithelium. Dr. James Dunlop investigates the Excretion of Oxalic Acid in Urine and its bearing on

Digitized by Google

oxaluria, and also the Action of Large Doses of Dilute Mineral Acids on Metabolism. He shows that these acids have a marked diuretic action, that they increase the total acidity of the urine, and produce an increase in the excretion of nitrogen and of soda. There are twelve articles on pathological subjects, amongst which may be mentioned the following:—Dr. Ralph Stockman on Iron in the Liver and Spleen in Various Diseases; a case of Pernicious Anæmia; the Experimental Production of Anæmia in Dogs; and the Treatment of Chlorosis by Iron. The pharmacological articles include one on Catha Edulis, and another on Viburnum Prunifolium (Black Haw) by Dr. Theodore Shennan; one on Carbonic Acid Gas in Diseases of the Alimentary Tract, by Dr. A. L. Gillespie; and one on Malayan Arrow Poisons by Dr. Ralph Stockman.

JOURNALS AND REVIEWS.

Birmingham Medical Review.—Mr. T. L. Webb contributes a practical paper on Preserving Pathological Specimens for the Museum and for Microscopical Examination. He recommends Tores's fluid for large masses, perchloride of mercury for small portions requiring careful study, and dilute formalin where the process must be rapid.

Scottish Medical and Surgical Journal.—Dr. James Rorie, of the Dundee Royal Lunatic Asylum, publishes the first portion of a paper on Homicidal Insanity, describing some typical cases. Dr. A. H. F. Barbour (Edinburgh) writes on Bleeding in Pregnancy and Labour, and its Mode of Arrest. Dr. Robert Jardine (Glasgow) records a case of Persistent Hymen in a woman in labour; "the husband, who was a young man, did not seem to be aware that there was anything wrong."

Edinburgh Medical Journal.—Mr. W. Bevan Lewis, of the West Riding Asylum, contributes a long and elaborate histological paper on the Structure of the First or Outermost Layer of the Cerebral Cortex. Dr. P. McBride and Dr. A. L. Turner continue their articles on Naso-pharyngeal Adenoids. Altogether there are eight original communications.

Dublin Journal of Medical Science.—This number contains a further instalment of Dr. J. Knott's article on Angina Pectoris. Dr. H. S. Purdon (Belfast) has a short note on Ecphyma Globulus, a contagious skin affection of rare occurrence.

Revue Philanthropique.—The opening paper is by M. Jules Siegfried, who takes Working-class Dwellings for his subject. He first gives a short account of the work of numerous associations formed for the purpose of erecting low-rented dwellings, commencing with the Société des Cités Ouvrières de Mulhouse, founded in that town in 1851, and making a brief reference to English building societies and the operations of the Peabody Trustees. The greater part of his article is devoted to the Société Française des Habitations à Bon Marché, founded in the end of 1889. Professor Grancher, of the Hospital for Sick Children, writes on Disinfection in Home Nursing.

The Intercolonial Medical Journal of Australia.—The number of this journal bearing date April 20th, 1897, has among other interesting articles one describing a form of nerve degeneration in horses, especially of the optic nerves. The disease closely resembles tobacco amblyopia as seen in the human subject, and is most probably due to the eating of the native tobacco plant, though this point has not yet been satisfactorily settled. Dr. J. W. Barrett, who contributes the paper, sums up as follows: "The chief symptom of the disease is blindness, and the blindness is due to degeneration of the optic nerve. Tobacco would readily produce these symptoms, and apparently the tobacco plant grows in the affected areas." Dr. A. J. Wood relates a case of a Half-penny Impacted in the Œsophagus removed after localisation by the x rays.

In the *Phonographic Record* for June Dr. Lundie points out that flat-foot is not exclusively an affection of adolescence. Dr. Colborne sends notes of Ophthalmic Work in China; Dr. Given narrates a case of Paralysis of the Second, Fifth, and Sixth Cranial Nerves; and Mr. Peyton Beale, in a suggestive paper on Perforating Ulceration of the Appendix Vermiformis, draws attention to œdema of the skin over the region of the cæcum as pathognomonic of the lesion. As such cases are never seen before perforation this localised œdema, in Mr. Beale's opinion, is a sure guide to the source of the acute peritonitis which is present. Immediate laparotomy, quickly performed, with removal of the appendix, is the only possible treatment. Mr. Beale deprecates washing out the abdomen, and after allowing the pus to well out he plugs the wound lightly with iodoform gauze.

WE have received from Messrs. Henry Graves and Co., of Pall Mall, London, an artist proof of one of their recent publications—"Inasmuch as." The subject is a nurse holding a child in her arms. It is admirably executed, and likely to be popular. The price is one guinea per impression for the artist proofs, and 10*s.* 6*d.* per impression for the prints.

Analytical Records
FROM
THE LANCET LABORATORY.

ANTIKAMNIA AND SALOL TABLETS.
(J. M. RICHARDS, 46, HOLBORN-VIADUCT, E.C.)

ACCORDING to our analysis, antikamnia contains as its chief constituent acetanilide, or antifebrin—a well-known antipyretic—in association with caffeine, which may be supposed to exert a modifying and favourable influence over the action of the former drug, chiefly in counteracting its depressing effect upon the heart. Valuable as this formula may be as an analgesic and antipyretic in the treatment of neuralgia, rheumatism, &c., it has been further modified recently by the addition of salol, which, as a milder agent than salicylic acid, has been employed in acute rheumatism. The combination is doubtless a useful one, and we are glad to find that it is "offered to the profession" and not for indiscriminate use.

CHINOSOL SOAP AND POWDER.
(B. KUHN, 36, ST. MARY-AT-HILL, E.C.)

A year ago we expressed the opinion that chinosol, in view of the many advantages which it presented, would become of special service as an antiseptic, disinfectant, and deodorant. Since that time it has been somewhat extensively employed with excellent results. It presents the important advantages that it is not caustic, corrosive, or poisonous, while it is free from objectionable odour and it does not coagulate albumin. It will serve as an admirable substitute for iodoform, carbolic acid, or even the powerful antiseptic corrosive sublimate. Chinosol is a bright yellow powder, freely soluble in cold water, and possessing a faintly aromatic odour. It may be employed in the form of tablets for making up solutions of definite strength, and recently it has been incorporated with soap adapted either for medicinal or toilet purposes. The soap basis proved on examination to be perfectly neutral. Still more recently, crude chinosol powder and chinosol disinfecting powder, for ordinary domestic disinfecting purposes, have been prepared. Bacteriological experiments have shown chinosol to be a very powerful antiseptic, while practical experience has proved that it may safely be employed.

SERRAVALLO'S BARK AND TONIC WINE.

(ROBERTS AND CO., 76, NEW BOND-STREET, W.)

From clinical results published on the Continent this wine would appear to be of distinct value in chlorosis and anæmia. Its value in this connexion depends most probably on the assimilable nature of the two medicinal constituents, the presence of which our analysis has confirmed. The iron is present as an organic combination, while in spite of the presence of the principles derived from Peruvian bark the wine is commendably free from excess of astringent matters and is not at all styptic. It is a sweet, somewhat syrupy liquid of peculiar purplish colour, with a slightly bitter taste. Iron was found in important quantity in the mineral matter obtained on incineration of the residue, while ether extracted a bitter substance, which proved to be fluorescent in sulphuric acid, and which responded to the ordinary tests for alkaloids. Analysis gave further results as follows: Extractives and sugar, 21·05 per cent.; mineral matter, 0·25 per cent.; alcohol, by weight 13·0 per cent., by volume 17·17 per cent. The wine affords an agreeable way of presenting two valuable tonic agents.

HUMANISED MILK (GAERTNER'S PROCESS).

(FRIERN MANOR DAIRY FARM, LTD., 20, FARRINGDON-STREET, E.C.)

Nothing could be more satisfactory than the composition of this product or more excellent than its condition. It presents a composition practically identical with mothers' milk, and a sample kept some months in the laboratory remained sterile and perfectly sweet. The results of our analysis were as follows: Water, 88·65 per cent.; total solid matters, 11·35 per cent., of which 3·10 consisted of fat, 6·43 of milk sugar, 1·82 of casein, and 0·35 of mineral matter. The milk is prepared on the following excellent plan. Milk fresh from the cow is diluted with an equal quantity of sterilised water. The diluted milk is then submitted to rapid centrifugal force in such a manner as to effect the separation of two streams, one containing practically all the cream, and the other the skim milk along with objectionable particles such as hairs, dirt, sand, &c. To the creamy milk thus separated milk sugar is added in the proportion of from 3 to 4 grammes per 100 c.c. The result is then a product with an excellent proportion of fat, and of other constituents in accordance with the proportions found in mother's milk. It obviously presents very distinct advantages over cow's milk that has been merely diluted with water, and, what is of further importance, the process yields a milk which is free from objectionable impurities such as may act as sources of infection. We are not surprised to learn that this milk has given satisfactory results in actual experience of infant feeding.

ST. RONAN'S TABLE WATER.

(ST. RONAN'S WELLS AND MINERAL WATER CO., INNERLEITHEN, N.B.)

Excluding salt, this well-aerated water shows a remarkable freedom from dissolved mineral matter. It is peculiarly soft and fresh to the taste. Our analysis of the water was as follows: Total solid matter, 1·05 grammes per litre; common salt, 0·90 gramme per litre; bicarbonate of soda, *nil;* calcium carbonate, a distinct amount. The water is thus only slightly mineralised, while it is free from organic impurity.

OLD SCOTCH WHISKY (BRIG O' PERTH BLEND).

(MATTHEW GLOAG, 24, ATTWEL ATHOLL-STREET, PERTH.)

The flavour of whisky is entirely a matter depending upon the skill in blending, while its wholesomeness may be measured by the time the spirit has been allowed to mature. The above whisky, though of full alcoholic strength, possesses a delicate and soft flavour. It is further free from any excess of colouring matters and extractives. Analysis gave the following results: Alcohol, by weight 44·64 per cent., by volume 52·29 per cent., equal to proof spirit 91·64 per cent.; extractives, 0·12 per cent.; mineral matter, *nil;* acidity reckoned as acetic acid 0·016 per cent. This whisky is clearly a wholesome and well-blended spirit, possessing age, and is desirably smooth and mellow to the taste.

BYNIN AMARA.

(ALLEN AND HANBURYS, LIMITED, PLOUGH-COURT, LOMBARD-STREET, E.C.)

This excellent preparation is a distinct advance on Easton's syrup. Not only does it contain the phosphates of iron, quinine, and strychnine unimpaired, but the vehicle for their palatable administration is, as our experiments have shown, a powerful digestive of farinaceous food. This vehicle is bynin, or liquid malt, which exhibits a powerful liquefying and converting action upon starch. Bynin amara is a thin brown syrup of not unpleasant though decidedly bitter taste. It contains no objectionable preservatives, and presents the medicinal ingredients of the excellent formula of Easton's syrup in correct ratio and in approved form. We succeeded in proving the presence of each and all of the tonic constituents indicated. The formula is such as is admirably adapted for the administration of one of the best tonic combinations known.

SOLVEOL.

(BURGOYNE, BURBIDGES, AND CO., 12 AND 16, COLEMAN-STREET, E.C.)

According to our examination solveol is a neutral solution of pure cresol. It is a clear, brown, thin liquid, perfectly miscible with water. On adding hydrochloric acid to solveol a crystalline buff-coloured precipitate results. Solveol on burning yields an ash of carbonate of soda. Its advantages as an antiseptic in midwifery and gynæcological practice, and for antiseptic irrigations generally, are evident when foremost amongst its properties are that it is non-poisonous and non-caustic, while it is said to be not incompatible with albumin, &c. The merit of the preparation appears to be that it represents for the first time a neutral aqueous solution of cresol, the practical application of which hitherto has been made inconvenient and unsatisfactory by reason of its insolubility.

BYRRH WINE.

(VIOLET FRÈRES, 68, CHEAPSIDE, E.C.)

Our analysis of this wine was as follows: Alcohol, by weight 16·46 per cent., by volume 20·24 per cent.; extractives with sugar, 13·86 per cent.; and mineral matter, 0·23 per cent. Byrrh is a pleasant, somewhat full-bodied wine, with a distinctly bitter flavour. On further examination this flavour would appear to be due to the presence of tonic bark extractives. On extraction with ether a powerfully bitter residue was obtained which responded to tests characteristic of cinchona constituents. The wine is free from injurious bitters and serves as an agreeable and wholesome tonic and stimulant.

VAN HOUTEN'S PURE SOLUBLE COCOA.

(C. J. VAN HOUTEN & ZOON, WEESP, HOLLAND.)

It is a widespread but very erroneous notion that certain of the excellent cocoas manufactured in Holland contain added alkali. This impression has been mainly due to an error of interpretation of certain results afforded on analysis. As is well known, cocoa in its natural state or in the form of crushed bean is quite unfit for food. Cocoa, therefore, must be prepared. The first step in this process is to eliminate as far as possible the excess of highly indigestible fat, which is generally done by expression in hot bags. After this process the cocoa generally contains about 30 per cent., instead of over 50 per cent., of fat. It may still be considerably improved for dietetic purposes by so preparing it that it may be made more soluble in, but in reality more miscible with, hot water, milk, or other fluids. With this end in view the simple addition of an alkali, as carbonate of potassium, or, as in the German method, of ammonia, has been suggested. From the dietetic point of view, as was pointed out in THE LANCET

Digitized by Google

of June 20th, 1896, this resource is distinctly objectionable. By Van Houten's process (the original Dutch method) a real improvement in the manufacture of cocoa which considerably added to the dietetic value of the product was effected. In this process the cocoa is not at any time or in any way prepared or treated with carbonate of potash, ammonia, or other alkali. The impression that it was so treated arose from the fact that on burning the cocoa so prepared a strongly alkaline and an increased ash was obtained. As a matter of fact, the decoction of Messrs. Van Houten's cocoa shows a faintly, though distinctly, acid reaction. It is just as logical to conclude that claret contains free alkali. Claret is of course strongly acid, but on burning the acid residue of the wine a strongly alkaline ash consisting of potassium carbonate remains. The important improvement in the dietetic properties of Messrs. Van Houten's cocoa consists in the enrichment of the cocoa by the addition of a trifling quantity of certain neutral salts, which, it is important to add, are perfectly normal constituents of the cocoa itself. Far from being objectionable, this procedure is fully justified by the evidence of experience as to the increased dietetic value of the cocoa so prepared. In a recent analysis which we have made the results distinctly indicate the advantage of this method. Thus this cocoa yields a decoction containing a maximum proportion of the valuable food constituents of the bean; and, of more importance still, these are presented in a condition more easy of assimilation and digestion than in cocoa not so prepared. The addition of a free alkali is, we hold, objectionable, because we have reason for believing that it would act unfavourably on the nourishing and stimulating cocoa substances. When cocoa, for example, is treated with alkali, an ammoniacal smell is at once evolved, which is probably due to the decomposition of the nitrogenous stimulating substances, as theo-bromine. In Messrs. Van Houten's cocoa, on the contrary, there is absolutely no free alkali, while the method of preparation undoubtedly adds to its nourishing properties and, more important still, to its digestibility. It has been said that one of the objects of adding alkali to cocoa is to partly saponify the fat and thus give the decoction a rich and frothy appearance. There is absolutely no trace of soap, we find, in Van Houten's cocoa. The important effect of Van Houten's process is, however, to increase the miscibility of the cocoa with water or milk, and to enrich it by the addition of a small proportion of its own natural constituents. An important economy is thus ensured. This treatment further tends to develop that fine aroma and flavour which make cocoa an acceptable beverage.

"APPLE JUICE."

(THE APPLE JUICE CO., 143, CANNON STREET, E.C.)

This is a fermented beverage like cider with a small alcoholic strength. Analysis gave the following results: Alcohol, by weight 5·25 per cent., by volume 6 55 per cent., equal to proof spirit 11·49 per cent.; acetic acid, 0·39 per cent.; malic acid, 0·43 per cent.; total extractives, 8 55 per cent.; mineral matter, 0·31 per cent. The excessive amount of volatile acid or acetic acid is an objectionable feature in this analysis. This result is borne out by the unpleasant sour taste, which is quite different from that of the fixed acids of the apple. Acetification has evidently set in, in spite of the juice being preserved, as we found, with salicylic acid. This fact, coupled with the quantity of saccharine matters present, renders this preparation not as wholesome as it might be.

EASTON'S SYRUP PALATINOIDS.

(OPPENHEIMER, SON, AND CO., 14, WORSHIP-STREET, E.C.)

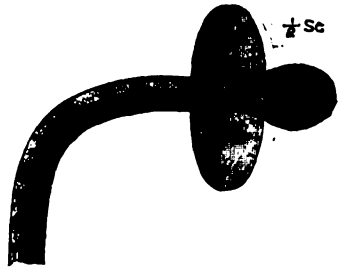
Palatinoids containing the equivalent of half a drachm of Easton syrup have recently been prepared. The contents consist of a bluish-grey, finely divided powder, containing phosphate of iron in an unoxidised condition, together with quinine and strychnine. The advantages of Easton's syrup in this form (that is, in a jujube, excluding the deteriorating influences of the air) are obvious. The formula is excellent and the constituents are preserved in their original state.

"CYMRALIS" TABLE WATER.

(R. ELLIS AND SON, RUTHIN, N. WALES.)

This effervescing water is bright, well aerated, and commendably soft to the taste. The water-supplies of North Wales are admirably adapted for the preparation of aerated waters since they are so pure. Cymralis, we find, is slightly and agreeably mineralised. The total solid matter amounted to 0·88 gramme per litre. It is slightly alkaline, the degree of alkalinity being equivalent to 0·25 gramme of bi-carbonate of soda per litre. This, coupled with the purity of the gas employed, accounts for the peculiarly soft flavour of the water.

SANITAS DISINFECTANT SOAP.



(THE SANITAS CO., BETHNAL GREEN, E.)

Sanitas has the distinct merit that though a decided disinfectant it has an agreeable smell. Further, it is quite compatible with soap. A specimen of sanitas soap recently submitted to us had somewhat the appearance and character of soft soap, but it proved to be a neutral soda soap, free from irritants. It evidently contains a good proportion of sanitas oil. For cleansing and detergent purposes it should answer admirably.

New Inventions.

AN EFFICIENT DRAINAGE PLUG.

FOR some two years past in cases where it has been necessary for me to make a permanent opening into any of the viscera, my attention has been specially directed towards devising some plan to relieve patients from the extreme discomfort which arises from lack of proper plug or conduit, and after repeated experiments I have now decided upon a very simple plan, which has proved so eminently satisfactory that I am sure it will meet the well-known difficulties of such cases. As shown in the diagram it consists of a tube with a flange and a pear-shaped expansion at the end, which is inserted into the viscus. This with a plug or clip answers well for gastrostomies. For the gall-bladder, &c., it is only necessary to attach a receiver. My experience with this plug has been so satisfactory in the already mentioned operations that recently I have tried it in a case of left inguinal colotomy, simply dispensing with the tubing portion and keeping it in position by a hollow padded colotomy truss; it is answering most satisfactorily. Simple as the contrivance is, it has only been arrived at after numerous experiments as to shape, &c., and correctness in these details is essential. I now find I can effectually plug without distending the opening, so that it is not necessary to be constantly changing the size; and, again, the action is in some respects automatic, as a sudden impulse, such as coughing and the like, tends to expand the pear-shaped extremity so that it neither allows of its own expulsion nor the escape of fluid by its side. The particulars I have mentioned govern the construction of the plugs when employed for any purpose, but it is essential to have them made of a suitable size and with suitably shaped necks to meet the requirements of each case. Such details can be had from Messrs. Down Brothers, 21, St. Thomas's-street, London, S.E., who have afforded me invaluable assistance in carrying out the experiments.

Cavendish-square, W. W. ARBUTHNOT LANE.

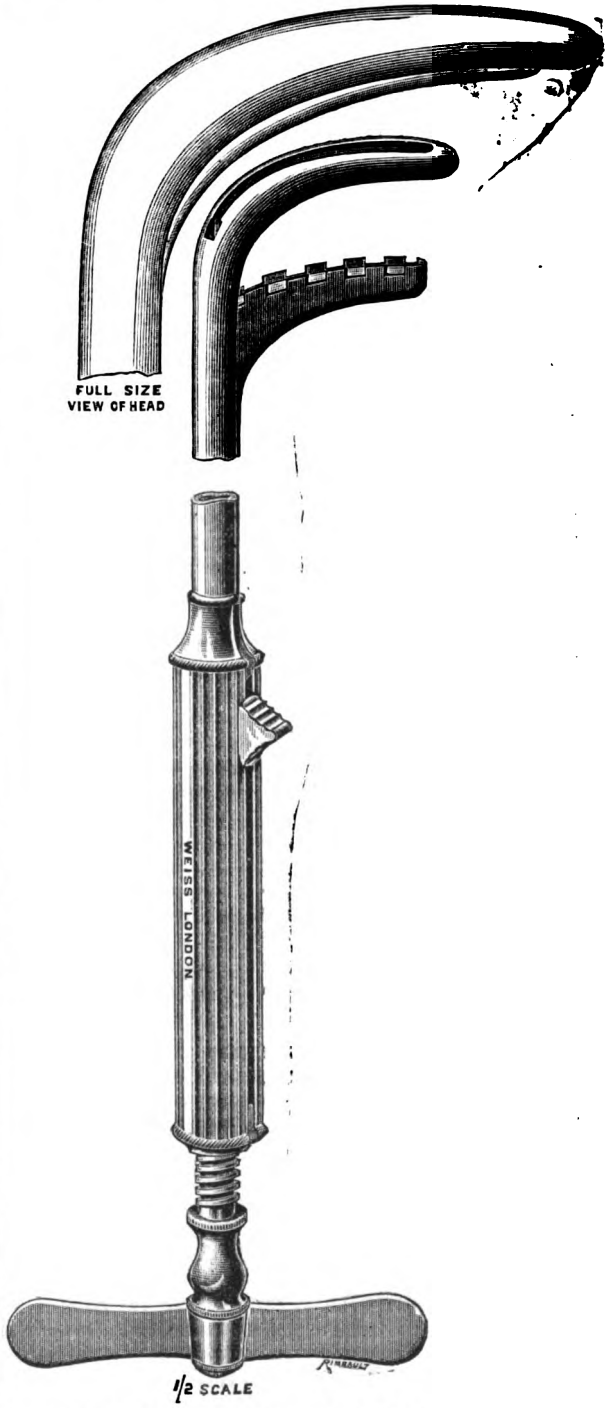
EMERGENCY INFUSION CANNULA.

MOST obstetricians carry with them the plain syphon douche as used at the Rotunda and other leading maternity hospitals. This douche is easily kept aseptic, it can be used with any vessel or receptacle and it reduces to a minimum the risk of air passing with the stream. All that is necessary to make it available for intravenous injection is to have a cannula to fit into the syphon tube. The cannula now described is enlarged at the upper end to prevent it from slipping, and the opening at the extremity which enters the vein is terminal instead of at the side, so as to avoid risk of air remaining in the blind end. Its case being made of metal can be rendered aseptic by boiling, and contains a couple of specific gravity beads indicating 1030 and 1028. The cannula is simple, inexpensive, and easy to carry. Its shape ensures its lying easily in the vein, it is always ready for instant use, and can be employed without a skilled assistant. The requisites for the operation are the syphon douche, the cannula, large and small jugs, a spoon, boiling water, cold boiled water if available or tap water, and, lastly, common salt. Scald thoroughly all utensils to be used and boil the spoon. Make a saturated salt solution in the small jug. In the large jug mix two or three quarts of water as near 98·4° F. as possible, tested by aseptic thermometer, or by pouring on the back of the hand. Add a specific gravity bead and pour in the salt solution till the bead rises to near the surface, mixing thoroughly with the spoon. The solution is now ready for infusion. Put the syphon end of the tube into the jug and start it running, then put the catch on the lower end of the tube, leaving it full and ready to run. Now expose the median cephalic vein, but do not open it. Next insert the cannula into the tube with the following precautions: First, let the stream run into the warm water in the basin to ensure all air being out of the tube. While still running insert the cannula under water.



That these precautions are necessary is proved by the fact that at any gynæcological clinique the ordinary vaginal glass nozzle may be seen at any time half full of air when the douche has been running some little time. With the cannula running, open the vein rapidly and insert the cannula still running; tie in if necessary. Observe the level in the reservoir and allow to flow till a pint and a half or two pints have entered the vein. Whisky or brandy should be added to the douche in the proportion of a teaspoonful to a pint. Messrs. Arnold and Sons, of 31, West Smithfield, are the makers.

W. C. HOSSACK, M.B., C.M. Aberd.

AN IMPROVED PATTERN OF "GIANT" LITHOTRITE.

I WOULD direct the attention of those interested in the surgery of stone in the bladder to an improved "giant" lithotrite, which at my suggestion, Messrs. Weiss and Son have devised and constructed, for dealing with very large calculi by perineal lithotrity. Surgeon-Captain Henry Smith, Civil Surgeon, of Jullundar, when stationed at Guzerat in the Punjab, devised the "giant" lithotrite described by me in my recent notes on stone in the bladder.[1] Some defects were found in this instrument, which have been remedied in the improved pattern figured in the annexed plate. Experience has taught us that suprapubic lithotomy has not fulfilled the early promise of the days of its revival, for the mortality which has followed it in cases of very large calculi occurring among males at the middle period of life is very considerable. There is therefore a growing consensus of opinion among surgeons practising in the East, where cases of very large calculi are of frequent occurrence, that perineal lithotrity, whether median or lateral, will in the near future supersede suprapubic lithotomy in dealing with this very important class of cases of stone in the bladder. There need, however, be no rivalry between perineal lithotrity and litholapaxy; rather should they be considered complementary one to the other. This improved instrument is made on the model of an ordinary Thompson's lithotrite, with the following exceptions. The male blade, instead of being joined to the screw at the handle end, is for greater strength left in two parts, the one terminating at the button, by means of which it is withdrawn, the other or screw portion working independently through a fixed collar at the end of the handle instead of by means of the usual forceps catch. In the place of the wheel it has a large winged handle 4¼ inches across, which gives an extra purchase in working. The dimensions of the instrument when closed are: Size over all, 18 in.; size of blades, 11 in.; size of hollow handle, 5 in.; size of stem, No. 20; size of stem at angle, No. 25½; size of point, No. 16. The jaws stand 2¼ in. for female

[1] THE LANCET, Jan. 30th, 1897.

Digitized by Google

and 2 in. for male blade above the shaft, and open sufficiently wide to take a stone of a diameter of over four inches. This instrument can be readily passed into the bladder through a small lateral incision in the prostate, or through an incision made as in median lithotomy, and it will readily break up a hard calculus weighing between six and eight ounces. The calculus thus crushed can be withdrawn from the bladder by forceps, or removed by means of an aspirator attached to a very large evacuating cannula, according to the predilection of the surgeon. The operation is completed in a short space of time, a matter of vital importance in such cases, and the neck of the bladder and prostate are not strained and bruised in an endeavour to extract a large calculus whole through the perineum. I feel confident that the mortality which has hitherto followed suprapubic lithotomy in dealing with very large calculi occurring among men at the middle and advanced periods of life will be greatly diminished by carrying out a perineal lithotrity in such cases.

St. James's-square, S.W. D. F. KEEGAN, F.R.C.S. Eng.

ASYLUM REPORTS FOR 1896.

Nottingham Borough Asylum.—On Jan. 1st, 1897, the number of patients amounted to 601. The accommodation provides for 585 patients, so that the asylum is overcrowded, and the position so created constitutes a serious difficulty to the management. Plans for enlarging the buildings have been passed, the asylum committee are anxious that the work should be commenced, but the Council refuse to move in the matter. In his report Mr. Powell, the medical superintendent, remarks that if the present progressive rate of admissions continues it will be necessary either to refuse fresh cases or to transfer chronic cases to some other asylum, although he confesses he does not know where the requisite accommodation is to be found. Every effort is made to discharge suitable cases to the care of relatives, but, as in all large towns, the conditions are unfavourable for maintaining and caring for chronic lunatics in their own homes, and it frequently happens that they are speedily returned to the asylum as unmanageable. In referring to the recent special report of the Lunacy Commissioners regarding the alleged increase of insanity, Mr. Powell states that, taking into consideration the whole of the causes of accumulation adduced by the Commissioners, he is unable to satisfy himself that they altogether explain the very large increase in the population of his asylum, and he is reluctantly obliged to conclude that in Nottingham there has undoubtedly been a substantial increase in the incidence of insanity in recent years. During the year 1896 there were 168 admissions, 65 recoveries, and 49 deaths. A feature in the admissions was the large preponderance of melancholiacs, both male and female, and 26 of the cases were directly attributable to mental anxiety due to adverse circumstances, domestic trouble, &c. Intemperance in drink accounted for 32 cases; 21 patients died from general paralysis; and 44 post-mortem examinations were made. The Commissioners in Lunacy report favourably on the management of the asylum.

James Murray's Royal Asylum, Perth.—Dr. Urquhart's remarks are always instructive, and this report forms no exception to the rule. He favours early discharge, and states that in face of a threatening relapse in a convalescent patient the question must be anxiously considered whether immediate removal from asylum surroundings is not the best course in his interests. In discussing the question of chronic alcoholism Dr. Urquhart makes some pertinent remarks, and in view of pending legislation his words may be quoted with advantage: "Twelve patients suffering from the results of chronic alcoholism were admitted. This is a larger number than usual. To it should be added one whose treatment was necessary on account of her succumbing to opium habit. There is no practical difference between these two classes—they seek oblivion, and it matters little whether the poison be whisky or morphia. A few were habitual drunkards, but the great majority were driven to excess by worry and consequent failure of mental health. The usual train of causes, in fact—first, an inherent weakness; second, a period of stress; third, a consciousness of failure and an endeavour to mend matters by calling in the powers of darkness to aid—excess and ruin in the end. A new heaven and a new earth must arise before this tale of misery is complete. I offer no suggestion other than has been approved by experience—the amelioration of social conditions. This includes a wider and deeper recognition of the laws of health, a wider and deeper appreciation of the interests of humanity. It cannot be in the interests of humanity that habitual drunkards are permitted to work their own destruction and the ruin of their families without such legal restraints as are imposed upon other dangerous members of society; and it bears especially hard upon those who become inebriates by reason of the inherited weakness of their physical and mental constitution. The times are ripe—indeed, over-ripe—for the wholesome restraint of those who are thus bent on ruin"—The value of the use of thyroid extract is exemplified by the recovery of a patient who suffered from a sharp attack of mania, followed by secondary dementia of sixteen months' duration. The Lunacy Commissioners (Scotland) record their appreciation of the excellent order of all parts of the asylum and the satisfactory condition of the patients.

Glasgow Royal Asylum, Gartnavel.—During the year 1896 there were 112 admissions, 41 recoveries, and 31 deaths. Brain diseases were, as usual, by far the most frequent cause of death. The mean age at death was fifty-four years. Dr. Yellowlees is of opinion that the apparent increase of insanity is due to the fact that many brain conditions—such as imbecility, senility, and childishness following paralysis—which were not formerly regarded as insanity are now classified under that category. His conclusions regarding the prospect of recovery in insanity, omitting cases of imbecility or of mere senility, are broadly stated thus: Of twelve persons attacked by insanity, one half will recover and the other half will not recover; of the six who recover, one half will remain permanently well, while the other half will become insane again once or oftener in the course of their lives, and will eventually die insane. This is in accordance with the views expressed by the late Dr. Hack Tuke after a minute study of available statistics. The Commissioners state that the asylum is conducted with great ability and that it well deserves the confidence of the public.

Royal Lunatic Asylum, Montrose.—In his report Dr. Howden complains that many of the patients were admitted in a dying condition, and expresses the hope that the new Form of Certificate of Emergency issued by the General Board of Lunacy (Scotland), in which a medical man is required to certify that the patient is in a sufficiently good state of health to be removed to the asylum, will prove a check to the practice of sending patients in a dying condition. With regard to the allegation sometimes put forward that asylum attendants are liable to become insane, Dr. Howden's experience leads him to believe that this is an entirely erroneous impression. He has met with cases, however, outside asylums where the association of the sane with the insane seems to have had a prejudicial effect on the former. He gives several instances where this has occurred. The death-rate amongst the male patients was higher than usual, but was due to the causes already stated. The wards are somewhat overcrowded, but the resulting evils are diminished as far as possible by careful attention to ventilation and sanitation, and by giving the patients abundant exercise in the open air. Since the publication of this report Dr. Howden has retired from the active management of the asylum. He has had a long, useful, and distinguished career, and during his tenure of office the Montrose Asylum has occupied a leading position amongst the institutions for the care and treatment of the insane in Scotland.

Aberdeen Royal Asylum.—During the year 1896 the admissions numbered 207, the recoveries 95, and the deaths 55. Dr. Reid, in his report, calls attention to the large number of deaths at this asylum from general paralysis and from phthisis. On Aug. 3rd, 1896, a new hospital, without which no asylum can now be called complete, was opened. Its design and arrangements seem to be admirable in all directions, and provision has been made in a most efficient and liberal manner for the care and treatment of the sick, the acute cases, and the infirm. Dr. Reid, in directing attention to what may be termed borderland cases, very properly remarks that there are many such at large in the world who do not overstep the limit between sanity and insanity, as at present legally recognised, but who might, with much advantage to themselves and the community, be placed under some suitable supervision. "The institution continues to be managed with great ability and success" (Commissioners' Report).

THE LANCET.

LONDON: SATURDAY, JULY 3, 1897.

THE two English Medical Colleges have been appealed to by the medical men of Norwich and others, who are impressed with the conditions of medical practice as revealed in the existence of new combinations of friendly societies, of commercial companies that know no more of medicine than they know of law or divinity, catering wholesale for the medical attendance of the working classes and for many comfortable people who cannot be included in such classes. The Royal College of Surgeons of England has not yet given its opinion on the subject of canvassing and advertising for patients. It has excited hope, inasmuch as it has referred the question of its own powers in such matters for legal opinion and advice. But both it and the Royal College of Physicians of London have shown a marked reluctance to use their powers of censure and remonstrance against methods which, if used by any private and individual member of the profession, would render him clearly obnoxious to those by-laws of the Colleges which are supposed to provide punishment for unprofessional ways of procuring practice. Of such by-laws the following are specimens.

The Royal College of Physicians of London has this by-law:—

"No Fellow or Member of the College shall officiously or under colour of a benevolent purpose offer medical aid to, or prescribe for, any patient whom he knows to be under the care of another legally qualified medical practitioner."

It has another by-law, which enacts, among other things, "that if it shall appear that a Fellow or Member or Licentiate has ..... acted in any respect in a dishonourable or unprofessional manner ..... the President and Censors may call the offending Fellow, Member, or Licentiate so offending before them, and having investigated the case may admonish or reprimand or inflict a fine not exceeding £10," or for graver offences may report to the College, which may proceed to deprive the offending person of his Fellowship, Membership, or Licentiateship, as the case may be.

The Royal College of Surgeons of England has this by-law:—

"If any Fellow or Member of the College shall, after due inquiry, be judged by the Council to have been guilty of disgraceful conduct in any professional respect, he shall be liable to removal by resolution of the Council from being a Fellow or Member of the College."

The by-laws of other Colleges are not dissimilar. Thus the Royal College of Physicians of Edinburgh has the following:—

"Any Fellow, Member, or Licentiate who shall, after due inquiry, be judged by the Fellows to have acted in an unbecoming or unprofessional manner may be censured, or may be deprived for such time as the Fellows may determine of all the rights and privileges which, as Fellows, Members, or Licentiates, they may enjoy."

The other Scottish Corporations have similar by-laws.

And a by-law of the Royal College of Physicians of Ireland says:—

"Every candidate before admission as a Licentiate engages not to endeavour to obtain practice or to attract public notice by any unworthy means, nor to sanction the use of his name by any other person for such purposes, and in case of doubt to submit to the judgment of the College."

The Royal College of Surgeons in Ireland by Ordinance 36 enacts that: "No Fellow or Licentiate of the College shall seek for business through the medium of advertisement or by any other disreputable method."

There are two great evils complained of by medical men, which have been powerfully exposed in the series of communications by our Special Commissioner under the title of "The Battle of the Clubs." The one is the crowding of huge numbers of persons into one Association, to be attended by one or two medical officers for a low sum and under conditions in which proper attendance, and even diagnosis, is impossible. The other is the system of canvassing and touting by which crowds of persons are attracted to such associations, often from the care of their own private medical man, to whom they are quite able to pay reasonable fees. We admit that *primâ facie* it is a difficult thing for a medical corporation to dictate the pecuniary terms on which its Licentiates shall give their medical services, but it surely must be admitted that the corporations can judge of the conditions under which medical diagnosis and treatment are possible, and it is not unreasonable to require of them, in any given case where the conditions are such as to make them impossible, to use some of their powers of remonstrance and of censure. In regard to the offence of canvassing and touting their duty seems still more plain, whether we regard the letter or the spirit of the above by-laws. We anticipate the objection that the medical officers do not personally canvass or instruct the canvasser, but they are the servants of those who do use means to draw all sorts and conditions of men away from their advisers and into associations which make a sort of trade of medical practice. They accept from such associations appointments which constitute an introduction to practice—often to the patients of other medical men who are undersold. It is difficult to deny that this system of canvassing by associations threatens great branches of general practice with ruin or that the medical man who acts for the association is morally responsible for the system. Without his help it would be inoperative and ineffective. We do not wish to see the corporations act with haste, but we do wish to see them act with more force and firmness than they have hitherto displayed. Suppose these evils were to spread to the upper ranks of practice—that consultants to attract numbers lowered the guinea or the two-guinea fee to 2*s.* 6*d.*, and that they put themselves under commercial companies which canvassed and touted for them, would the corporations be as apathetic as they are? We think not. We do not doubt that they would find ways of maintaining the dignity of medical duty and of medical remuneration. They have a far larger obligation to use what powers they have, and if these are inadequate to seek stronger ones, to compel their Licentiates in the larger field of general practice to refuse appointments which turn medical practice into a farce, and

Digitized by Google

which involve canvassing and foul play to the private practitioners of the country.

IN India there is no such thing as medical registration, nor is there any Medical Act in that country to govern or regulate the conduct of practitioners of medicine, to protect them in the exercise of their calling, or to defend the public from the practices of quackery in its many guises. That such a state of confusion and irregularity should exist and continue in a dependency of the British crown where medical education has been more or less supervised by the State for the past fifty years is most surprising, and it is all the more regrettable in view of the fact that the medical societies and medical associations, as well as the medical and lay journals of India, have one and all from time to time during the past decade represented to the Government of India the urgent need that exists for some form of medical registration in the mutual interests of the profession and of the people.

Medical education in India aims at providing the public and the State with varying classes of practitioners. Thus, the Indian Universities, the qualifications of which are recognised by the General Medical Council of Great Britain and are registrable in this country, confer on their graduates the degrees of M.D., M.B, and L.M.S. Their preliminary educational standard is a degree in arts, and their professional curriculum, which is a very complete one, has always required a five years' course of study. Outside the Universities, India provides no other qualification which ranks as a registrable diploma, nor indeed, is there any other diploma which from its intrinsic merit could at present deserve the status of a British registrable qualification. So that for the present, so far as registrable qualifications on the basis of the General Medical Council's requirements are concerned, we have only to deal with the graduates of the Indian Universities. Having obtained what are State passports to practise medicine, having paid into the State coffers the cost of a full curriculum for a period of five years, and possessing a guarantee from the Government of India as to their ability as physicians and surgeons, it seems only reasonable to expect that they should receive some protection from the State, such as is afforded to duly qualified practitioners in this country by the provisions of our Medical Acts and system of registration. There ought to be no difficulty in legislating specially for medical practitioners in India, but if there are obstacles in view of the varying grades of otherwise orthodox practitioners and the confusing number of unorthodox indigenous classes of the Vaid, Kobiraj, and Hakimi sects, then an easy way out of the difficulty would be to extend the Colonial Section of the British Medical Register to India, and enforce entrance to its rolls on all Indian University graduates by making the enjoyment of certain rights and privileges conditional on registration. If, for example, the Government of India were to promulgate an order in its *Gazette* that for the future no registrable practitioner in India could obtain any State appointment or have any legal status unless his name was to be found in the Colonial Section of the British Medical Register an immediate blessing would be conferred on both the public and the medical profession in India, without any additional legislation. A Section of the Medical Act is now applicable to India, so that registrable qualifications have the right to immediate registration, and therefore it is only necessary, as it seems to us, for the Government to enforce submission to the conditions of the existing British Medical Register. The Indian medical profession would thus obtain a definite status in the body politic. This step would place the professional conduct of Indian medical graduates under the cognisance of the General Medical Council, and prove a salutary measure, raising the tone of Indian medical practice. It seems clear that this is a matter in which the General Medical Council might legitimately take action by inviting the Government of India to consider this method of registration in the interests of medical education and for the advancement and protection of the medical profession in that country. This necessary interference by the General Medical Council may, with some show of justice and urgency, be claimed for a body of our brethren who number some thousands on the rolls of the Indian universities, and who from the absence of specific legislation in medical matters in our Indian Empire are virtually devoid of legal status and absolutely without legal protection of their rights and privileges as properly educated and duly qualified medical men.

With regard to the extension of a system of registration to a large and important class of practitioners who are educated for employment in the subordinate services of the Indian Government, and to those who work chiefly among the poorer sections of the Indian people, they might still find suitable recognition and protection by their inclusion in a purely Indian Medical Register. It would, of course, be always open to these grades of medical workers to be admitted to the British Medical Register when their education and qualifications had been improved up to the necessary standard. We notice that in 189 a "Medical Register and Directory of the Indian Empire" was compiled by Dr. JAMES R. WALLACE, of Calcutta, in which all the various sections of the medical profession in India were embraced in their different grades. Some such compilation as this, if brought out under State authority or cognisance, would pave the way to a State system of registration. The question seems to us worthy of the consideration of the Government of India and of the provincial Governments of the Indian Empire.

COMPLAINTS reach us from time to time of the insanitary way in which some night shelters are conducted, and from private investigations which we have made we fear that these complaints rest upon a substantial basis. The Public Health and Housing Committee of the London County Council have on several occasions dealt with the matter casually, and with a view of obtaining more information they instructed Dr. C. W. YOUNG to inspect premises in London where the homeless are temporarily provided with night accommodation in rooms which they occupy in common. Dr. YOUNG'S report has now been printed with a prefatory note by Mr. SHIRLEY MURPHY, the medical officer of health of the administrative County of London, and the document is one which deserves careful perusal. A

Digitized by Google

mass of important information is presented in a succinct and orderly manner, and the fact that it comes from a body like the London County Council must disarm the criticism of those who assert that complaints made by private individuals in this connexion are actuated by bias and prejudice.

In addition to the large number of common lodging-houses which come under the provisions of the Acts applying to them there are in London a number of night shelters for the homeless poor where either gratuitously or at a charge ranging from 1*d*. upwards sitting or lying accommodation can be procured under cover for the night. These institutions are generally conducted by some religious body from the best of philanthropic motives, though not in all cases in the best of sanitary methods, and though good results may sometimes follow they are often attended with evils which far outweigh them. Although a charge may be made for the accommodation provided, the proprietors of these shelters do not professedly run them for a profit, and the buildings are exempt from the same sanitary supervision which obtains in the case of the registered common lodging-house. Of course, a medical officer of health can treat them as he does private premises, but practically he can only demand admission between the hours of 6 A.M. and 9 P.M.—a period during which the buildings are necessarily empty. He can obtain an order from a magistrate for a right of entry at any time it is true, but the process of applying for an order may give the shelter officials, if they are so disposed, ample opportunity of frustrating the good which might result from such order.

It cannot be denied, however, that whatever the evils of these institutions may be, they certainly do provide a home for those who cannot avail themselves of the better-class lodging-house, and who would otherwise either have to find shelter in the casual ward or remain throughout the night in the streets. If the shelters provided by philanthropic bodies were subject to the same supervision as the registered common lodging-houses it must be quite evident to all who have visited these institutions and listened to the statements of the officials themselves that accommodation for the homeless would be less adequate than it is even at present; for there is no doubt that some of the shelters are overcrowded, and consequently the existing provision would have to be lessened. By some it may be urged that the State has made provision for the absolutely destitute, and to a certain extent this is true. But the State provision at present is perhaps not all that could be desired, and it is an open question whether, after all, the casual system does not tend in the long run to aggravate an evil which it is intended to remedy. On the other hand, we must consider not only the individual but the community at large, and if some of these shelters are liable, as we believe they are at times, to become hotbeds of infection, owing to insanitary conditions both of the house and its inmates, the sooner these shelters are brought under more efficient control the better for all concerned. We have it on the authority of one who, if not the absolute head, holds an important position with regard to the management of a large proportion of night shelters, that the body with which he is connected is willing to loyally abide by whatever Acts are passed by Parliament to regulate the control of these shelters. This statement is significant; and it is to be hoped that the London County Council will adopt the suggestion of their medical officer of health and apply to Parliament for the amendment of the definition of a common lodging-house so as to bring shelters within the provisions of the Acts which apply to common lodgings let for profit.

WE wish to call attention to the very temperate and accurate description given by a correspondent in a letter in another column of the difference between the intention of the founders of the examination for the Fellowship of the Royal College of Surgeons of England some fifty years ago and the practical result at the present time. When founded the Fellowship was expected to be merely a higher grade for Members who wished to give a longer period to surgical study, to work hard at surgical anatomy, and to show themselves quite proficient in practical surgery. At the present time the primary examination for the Fellowship is at once the most difficult and the most uncertain examination in its results at which any candidate in the kingdom can be tempted to present himself. In the first place, the constitution of the Board of Examiners is quite anomalous. The examiners in anatomy are all Fellows of the College, and are, to a certain extent, unconsciously biased towards a limitation of the number who should also enjoy their privileges. The privileges of a Fellow are very obvious ones. He can vote for those Fellows who desire to sit on the Council of the College and can alone be elected to a surgical office in most of the London and provincial hospitals. Candidates with University degrees in surgery who are not Fellows of the Royal College of Surgeons of England are debarred by the by-laws from holding office as surgeons or assistant surgeons in the largest and most important of all our English hospitals. This rule at once secures a close corporation. In the next place, not being able apparently to find amongst its own Fellows a sufficient number of advanced physiologists to examine at a high standard for this qualification, the College enlists from outside some of the latest investigators into this ever-progressing, or at any rate ever-changing, branch of science, and with what result it is easy to imagine. Further, another element of confusion is the inclusion of comparative anatomy. Attendance on a course of lectures on this subject is required from every candidate, but no syllabus is drawn up for his or his teacher's guidance. Generally none is required, but any examiner, acting on his individual knowledge and proclivities, may ask any morphological or developmental question that he may choose. The candidate must be possessed of an encyclopædic memory, for the practical examination is *nil*, and the *vivâ voce* depends on the personal equation of each examiner, whilst the written part is the great feature of the competition, and the questions set have rarely any bearing on surgery or practical surgery, but are based on questions of pure anatomical and physiological details. Can we wonder that under such circumstances over 70 per cent. of the candidates are rejected? Everything in the examination is against the examinee, and the time limit in the *vivâ voce*, with the limited numbers of

Digitized by Google

the questions—four in each paper and no choice—proves the last straw to many a deserving and hard-working student and practitioner. Surely such an education in "cram" is the worst that could be devised for our future surgeons, and would cause the surgeons of the past generation to "turn in their graves" if they could only know what had become of their excellently practical scheme. The examination is at the present time only a field for intellectual gladiators in competitive examinations to exhibit their abilities, and is absolutely devoid of consideration as a training ground for practical surgeons. It is now quite an anachronism, and the examination has still more glaring defects than those which we pointed out some twenty years ago. Collegiate privileges should be divorced from a pure examination test, and the surgical appointments at our hospitals should not be restricted within such narrow limits as those which seemed expedient to our predecessors in the earlier days of the century.

Annotations.

"Ne quid nimis."

THE DIAMOND JUBILEE COMMEMORATION.

THE rejoicings and spectacular displays commemorative of Her Majesty's reign of sixty years have ended, and the nation may look back upon the occasion with sincere satisfaction. Such a spontaneous demonstration of affectionate loyalty and of unity has probably never taken place before in the world's history. Responsibility and power must go hand-in-hand, and it would ill-become the people of this country to recognise the power and forget the responsibility of the British Empire. What have been the most striking reflections to which this Jubilee has given rise? In the first place, we owe it to the peoples and Governments of the rest of the world to state that the most gratifying and brightest fact in the history of this commemoration has been the sympathetic magnanimity which they have displayed towards the Queen and this country. On all sides the expressions have been most generous and cordial on the part of other powers and peoples, and the fact has left behind it a peculiar sense of grateful appreciation; and, in truth, there was nothing aggressive or of menace in all the display that has been exhibited. This is a free country, and its inhabitants are a law-abiding people with a keen love for freedom and good government everywhere. It is not a mere phrase, it is a fact, that the British Empire is peace. The admirable organisation and excellent arrangements by which everything has passed off so well, and the splendid conduct of the people—their enthusiasm, cheerfulness, good temper, and forbearance—must have struck everyone. The Queen is a wise sovereign and a good woman, and her people were determined, so far as their conduct was concerned, that nothing should frustrate or mar the effect of the expression of their loyalty and trust, and Her Majesty manifestly must have felt in full force the pride and pathos of her position as the vast crowd spontaneously burst forth in singing the National Anthem and compelled the bands to adopt and follow their lead. The people felt that the Queen had never for dynastic or selfish purposes, deceived or distrusted them, and the throne of England, supported on the shoulders of a democracy, is not only the most stable throne in the world, but the occupants of all the others really owe it a debt of gratitude in this respect for the strengthening influence of the fact. Then, again, there was a unity of sentiment, spirit, and purpose running through all classes, from the costermonger to the peer, as they recognised the emblems and tokens of the vast Empire in the streets of London—the roots extending from Great to Greater Britain—of which the Queen was the representative and symbolised embodiment. That the President and people of the United States should have been foremost in their expressions of kindly sympathy was to be expected and could be counted upon, but that France, our nearest neighbour, should indulge in no word of envy, jealousy, or cynical coolness towards this country, but, in the spirit of that old chivalric generosity which has always characterised her, should have "let herself go" in kindly expressions of friendly admiration was most gratifying. The easy, pleasant manner in which the crowd obeyed the police, protected women, and showed their kindly disposition to children; the way in which they abstained from smoking in order to diminish danger and annoyance; the fact that the number of cases at the London police courts following the Jubilee procession did not exceed those of an ordinary Monday morning; and the absence of crime, and of all panic and serious accidents, may well make us proud of the conduct of those present in the streets of London on that occasion. The police, the navy, the military, the London County Council, and the people have, one and all, played and performed their allotted parts most creditably; nor do we believe that the effect of all that has taken place during the acute stage of jubilation fever through which we have just been passing will be lost on those from abroad who have honoured us with their presence in this country.

THE ATTITUDE OF THE MEDICAL PROFESSION TOWARDS THE PROVIDENT PRINCIPLE.

A THOUGHTFUL and fair paper on Provident Dispensaries and the Medical Profession, by Mr. Charles H. Warren, secretary of the Metropolitan Provident Medical Association, is published in the *Charity Organisation Review* of February, 1897 (Longmans, Green, and Co.), and should be read by all medical men. It deals with the subject of provident dispensaries and the principles on which they should be managed and governed, as well as with the causes which have hindered their success, which may be said to be principally two—first, the competition of free hospitals, and, secondly, lack of support from the medical profession. The first cause of the slow progress of provident dispensaries, the competition of hospitals, is obvious. Such dispensaries are found not to thrive in the neighbourhood of free hospitals, though, by way of proving the rule, there is one exception just opposite the London Hospital. Mr. Warren gives a striking fact in illustration of the unfitness of a large proportion of hospital patients. It is the result of an experiment for which the Hospital Saturday Fund and the Metropolitan Provident Medical Association must have the credit. The Hospital Saturday Fund found the applications for letters for chest hospital treatment so numerous that additional letters had to be purchased. They agreed with the hundred medical officers of the Provident Medical Association to examine cases applying for such letters and to certify fitness for such relief. Each applicant was required to produce a certificate before getting a chest letter. The result was that only 226 returned with the necessary certificate. No less than 238 did not see fit to submit themselves to examination. Of the total number applying for chest letters only 152, or 32 per cent., were considered proper cases for hospital treatment; the remaining 68 per cent. were kept away from hospitals because of their unsuitability, and for those treated at the dispensaries the medical men have received such remuneration as the rules of the dispensaries provide. Mr. Warren is quite right in believing that there has been a coldness of late years on the part of medical men

Digitized by Google

towards provident dispensaries and in saying that till this is removed they cannot succeed. The admission of unfit members, the poor terms of remuneration, and the practice of more or less touting or canvassing are the explanations. He asserts that in all the more recent provident dispensaries there is a wage limit. We are glad he entirely approves the wage limit, though he says it must vary in different districts. He thinks medical men in organising provident dispensaries are tempted to make the wage limit too low and the fees too high. Whatever their temptations, they have had no success in getting too high fees. The objection to convassing he meets by saying that more or less of it is indispensable, but that the names of the medical men should not be published. It is a poor satisfaction to a medical man who has lost a private patient that he was captured by an advertisement or handbill of a dispensary not containing the names of the medical officers. As to the fees to be paid, he defends the scale of the committee of which the late Sir Spencer Wells was chairman. But it is too low in these days of high wages and costly medical education. Fourpence-halfpenny or sixpence per attendance is an entirely absurd sum for a medical consultation, and it will only be by making every visit a true consultation, however short, that the character of medical attendance among the working classes will be maintained. It is most essential that the medical profession should accept the provident principle. If they do not they will only play into the hands of competing hospitals and commercial companies. But the advocates of provident dispensaries must conceive more adequately of the value of medical service.

GARBAGE AS AN AUXILIARY SOURCE OF ELECTRICITY.

IT is interesting to notice how problems directed to the disposal of noisome things have been at length grappled with from the point of view of utility also. The enormous waste of material of priceless agricultural value, as sewage must be, has been a standing reproach to that section of our administration which deals with great sanitary questions. There is hope, however, even in this matter that sewage will no longer be ruthlessly disposed of but turned to excellent account. And we have been learning all this time that nature provides us with myriads of engineers in the form of microbes to do this work if only we will give them a chance, or, in more scientific terms, place them under conditions favourable to their operations as scavengers. Dust again has been a source of abomination to the public and to every municipal authority since the days when it was rejected as no longer economically useful by the brickmaker and house builder. At last fire was employed, in the form of the "destructor," to put an effectual end to its tendency to putrefy and hence to corrupt the air. So far, so good; but this method aimed, like the thousand and one methods of chemical treatment in the case of sewage, at mere disposal only, and the removal of a nuisance without the least pretence to utility. The "destructor" was not, however, in all cases a satisfactory machine, since in the energy of combustion a shower of dust and ashes was produced and scattered in the immediate neighbourhood of the shafts. The days of the non-utilitarian "destructor" are, however, numbered. It should give way shortly to a "converter." This at least appears to be the practical teaching recently afforded by the energetic vestry of St. Leonard, Shoreditch. The employment of garbage as auxiliary fuel to feed the engines driving dynamos for the production of electric light has been tried elsewhere before, but not satisfactorily either from the engineering point of view or the point of view of economy. The difficulty has been to utilise all the heat of combustion at all times, and to prevent formation of lava-like clinker. Judging from the satisfactory reports in the press of the Shoreditch installation, which was started by Lord Kelvin, these difficulties appear to have been successfully overcome. As far as we can gather, the success of this plant appears to depend upon an improved system of thermal storage, so that the heat accumulated by day may be stored and turned on to contribute to the increased requirements of the night. Everyone will hail with great satisfaction a step in advance in this direction, and we may take it that the presence of Lord Kelvin at the opening ceremony at Shoreditch on Monday last is some guarantee of a successful issue. In distinctly enthusiastic terms he congratulated the members of the vestry upon the energy and courage they had shown in carrying out ideas which had not previously been tested. It was an example, he added, of the amalgamation of scientific knowledge and forethought with mechanical engineering and skill.

THE PRINCE OF WALES'S HOSPITAL FUND.

A LETTER which appeared in the *Times* of June 29th from Mr. B. Burford Rawlings is well worthy the attention of all those who have the interests of our hospitals at heart, and especially those who, from want of thought more than from want of means, have not contributed at present towards the above fund. The annual subscriptions at present, says Mr. Rawlings, consist of £20,000 contributed by less than 5000 households instead of £112,500 contributed by 225,000 households. Mr. Rawlings pleads for a more personal element to be imported into the matter. The days of mediæval charity, when men gave houses and lands for the support of the poor and needy, have, we fear, gone by, and nowadays the only way of getting subscriptions is by persistent touting. A system of this kind well organised and under "distinguished patronage" would we feel assured open the purse strings of many who now do not subscribe at all. It is curious if we look at any subscription list to see the same names occurring again and again. Well-known wealthy men and a certain amount of anonymous subscriptions, which latter probably always come from the same persons, are to be found, but the rank and file of fairly well-to-do people are absent. It is a hard saying, but the majority of subscribers to-day want a show for their money; and whether they are working men subscribing to a hospital or others who demand letters, the position is the same—there is always the dread present to the hospital secretary's mind of the subscription being withdrawn. Perhaps if a sort of hospital Primrose League could be started it would solve the difficulty.

THE NATURE AND LOCATION OF LUMBAGO.

MR. JONATHAN HUTCHINSON[1] asserts, contrary to prevalent opinion, that the pain of lumbago is not in the lumbar muscles, or, indeed, in the loins at all; he has invariably found it to be in the sacral region, or in the sacro-iliac synchondroses. In the latter position it may be on one side only, but this is exceptional. There is so much peculiarity and definiteness about the pain of lumbago that it is a pity that it should not become an acknowledged type. Probably pain of a similar character occurs in other regions of the body. There are never any objective phenomena, and often there is little or no tenderness. It is a sleeping pain, and the thing that wakes it is not pressure, but movement. In many cases so long as there is no movement the pain is entirely absent, but the slightest attempt to alter the position of the back produces agony. The pain itself may be compared to sheet lightning; it is not exactly a single flash, but it broadens out and quivers from side to

[1] Archives of Surgery, April, 1897, p. 97.

Digitized by Google

side across the affected part, and leaves a hot glow behind it. The first attack is often very sudden and disables its victim for the moment. As it is one of the large group of phenomena which go with the inheritance of gouty tendencies and exposure to the exciting causes of rheumatism it will often not be present alone. Sciatica, hip-joint arthritis, and affections of the spinal articulations are amongst its most frequent companions. In these cases we must separate their several elements. Lumbago is variable and transitory, whilst the pain of the other affections is usually more persistent and independent of movements. Lumbago in severe forms may shoot down the back of the hips and simulate sciatica; but unless the sciatic nerve be affected it does not pass far down the limb, nor is it attended by pain over the nerve trunk or wasting of the muscles. The liability to lumbago once experienced usually lasts the rest of life, and is influenced by season, weather, diet, and exposure, just as gout and rheumatic gout are. Its subject may be quite free the greater part of the year, but suffer for a month or more in early spring. The treatment consists of active exercise, care in diet, and warm clothing, especially across the hips. During the presence of pain the sufferer should, if possible, move about, even if he can only do so with assistance and bent almost double. After a time he will find the pain subsiding. In severe cases, unless the patient is unusually resolute, exercise is out of the question. Then recourse must be had, if not to Graves's favourite plan of cupping, to blisters, sinapisms, or the use of heat locally. Internally alkalies, aconite, and colchicum should be given. The patient should drink plenty of hot weak tea. As to the structures actually involved, Mr. Hutchinson has no doubt they are the ligaments of the sacrum and the cartilage between the sacrum and ilium—the latter as the result of self-observation. The pain is too deeply seated to be located in the muscular fascia and too peculiar to belong to a structure so general.

POST-GRADUATE FACILITIES IN RUSSIA.

AT the ten Russian Universities and at the Army Medical Academy in St. Petersburg there are facilities for post-graduate study. Courses varying from one to three months are held in various special subjects, and the fee charged is a small one, averaging about half a guinea. All medical graduates may attend quite freely the wards of the clinical hospital or infirmary attached to the university, and there are abundant opportunities for graduates desiring to do original scientific work in the laboratories attached to the universities, the cliniques, and other hospitals. In St. Petersburg there is in addition a very handsomely equipped hospital reserved entirely for the clinical use of medical men; it is, in fact, a graduates' clinique. This is the Helena Institute, or, to give it its full title, the Imperial Clinical Institute of the Grand Duchess Helena Pavlovna. It is named after a sister of the Emperor Nicholas I., one of the most active, charitable, and philanthropic workers of her time, who among other good deeds introduced the practice of nursing by women into Russia, and whose memory is still green. The Institute has 108 beds; it receives poor patients freely; others pay from 10 to 100 roubles a month, according to the accommodation. The present director of the Institute is Professor Skliffosofski, who has been selected as President of the International Medical Congress in Moscow. Attached to all the Russian Universities and the Army Medical Academy are a considerable number of scholarships (stipendia) either instituted by the Government or by private individuals, the holders of which are entitled to remain attached to the university for one, two, or more years, and to carry on original work in the laboratories and wards. A certain number of graduates are annually sent abroad at the expense of the Government to study at foreign universities and hospitals. This applies not only to recent graduates, but also to men high in the profession, university professors, and others. In addition the *zemstvos*, or local governing bodies, to each of which is attached either a medical board or a medical officer, frequently send (at the expense of the *zemstvo*) their medical officials to St. Petersburg, Moscow, or some other university town to spend three, four, or six months in the wards and laboratories there. This admirable system enables a provincial medical officer to keep in touch with the advances made in medical science. The Government encourages it by granting sums of money from the Treasury to assist the *zemstvos* in carrying out the system.

AFTER MANY YEARS.

THE City has lately had to deplore the loss by death of two medical men who were prominent inhabitants and the holders of important posts. The first, Mr. Charles Hogg, F.R.C.S. Eng., who died at St. Leonards-on-Sea in his eighty-sixth year, was for many years medical officer to Merchant Taylors School, and used to live in Charterhouse-square. The second was Mr. Charles Hope Buncombe, F.R.C.S. Eng., who died in his eightieth year and who had held for more than twenty years the post of medical officer to the City of London Infirmary. It is wonderful to think of the changes, especially in preventive medicine, which these two gentlemen must have seen. Fifty years ago Smithfield and the neighbourhood was a perfect Inferno. The cruelty, the filth, and the absolute want of anything approaching to sanitation which were perpetually present in the market and the slaughter-houses can scarcely be believed nowadays, but if anybody cares for horrors let him read a series of articles which appeared in *Household Words* in the early fifties, entitled the "Cattle Road to Ruin." At present the City is perhaps the best drained, swept, and lighted city in the world, and the other parts of London are for the most part but little in arrear.

"SLY'S PATENT TRUSS."

THE sentence of eighteen months' imprisonment with hard labour passed by the Lord Chief Justice at the Oxford Assizes last week on Samuel Albert Sly, otherwise Albert Hodge, the owner of "Sly's Patent Truss," should prove a useful warning to the other rogues of his class who are daily defrauding the unsuspecting public by means of false and misleading advertisements and circulars. The quack is a firm believer in printer's ink and publicity, as he should be, for he knows full well that there are hundreds and thousands of the gullible public ready to swallow any rubbish that he may be pleased to provide if only he can find mediums to advertise it with sufficient boldness and indecency. The quack is also a firm believer in the written support of "grateful patients," and the majority of these parasites have hundreds of unsolicited "testimonials" in their possession, the originals of which, according to advertisement, can be seen on application. Should anyone be so unbelieving as to want to see the originals they are invariably as difficult to produce as were the man Sly's. Not that Sly's methods were quite bereft of originality. He scorned such stupid trickery as writing his own testimonials—a method which always must lack some little *vraisemblance* and which also requires the trouble of composition. Sly found it a far easier course to extract from the trade circulars of various truss-makers the most approvin criticisms of the medical press and the best genuine testimonials from patients, and to appropriate these as commercial and private testimony to the value of his own "truss." He merely altered the names of the places fro which the testimony emanated and the dates and signatures. Out of ten testimonials on his business circular nine were proved in evidence to have been thus "lifted," and yet,

Digitized by Google

humorous man, he put at the head of his circular an offer to show the orig nals on application! There was an extract from THE LANCET impressed into Sly's service, upon the strength of which, by the bye, the prosecutor, a mill manager at Blackpool, sent £5 for a truss. This particular extract appeared in our columns ten years ago, and was a commendation of a different appliance made by a manufacturer who is still in business in London. Sly added to the extract words which never appeared in THE LANCET, but the source of his inspiration was undoubted and indisputable. The value of "Sly's Patent Truss" may be gathered from the evidence given at the trial, one maker stating that it "was perfectly worthless," another that it "was not worth the brown paper it was wrapped in," and another that it "was a very bad thing altogether and not fit to be worn." And for this article £5 was the sum charged—about double the price of an ordinary truss—and to it complimentary things said about other and genuine instruments were calmly applied. Sly is no stranger to prison life, for he was sentenced at the Middlesex sessions, in the name of Albert Hodge, to seven years' penal servitude in 1888. He now goes to prison again, and we hope he will reflect upon the truisms contained in the opening sentences of this advertisement which we quote from an evening contemporary:—

Time proves all things. Honesty is the best policy. A hundred and seventy years ago one Sly set up his Truss Works in Oxford, and from that time down to the present the business has grown. Why? Because Sly's Improved Patent Truss, as worn by Sir Andrew Clark, and recommended by Sir B. W. Richardson, has been proved to be The Best on the Market. 44 Prize Medals, Diplomas, and Royal Appointments awarded. Write for particulars and Prices, Sly Bros., Oxford.—Advt.

The references to Sir Andrew Clark and to Sir Benjamin Ward Richardson constitute an outrage upon the memory of these eminent men; but Sly knew well that he was safe in holding out dead men as decoys. It is this particular piece of blackguardism, almost more than his misuse of our words, which makes us rejoice over Sly's fate and unable to enter heartily into the extravagant fun of the forty-four prize medals, the diplomas, and the Royal appointments. Yet the imagining of "Royal appointments" for a bogus truss shows imagination of no mean sort. This conviction should prove a salutary lesson to the dishonest individuals who do not hesitate to misquote THE LANCET to serve their own ends. They are not a small crowd, and many of them are known to us.

DEATHS OF TWO AMERICAN LEADERS IN MEDICINE.

WE offer our sincere condolences to the profession in America on the unexpected deaths of two of its most distinguished members as was announced in the last issue of THE LANCET. J. Lewis Smith, A.M., M.D., of New York, and William Thompson Lusk, M.D., LL.D., of New York, were equally pre-eminent in their respective departments of medical work. Dr. Lusk's book on the Science and Art of Midwifery has long been recognised as one of the best, if not the very best, treatise on its subject in the language, and it has been translated into several European languages and into Arabic. Dr. Lewis Smith's book on the Diseases of Children, of which there have been eight editions, might be spoken of in the same terms. Each author spared no pains—clinical, pathological, or literary—to arrive at truth in his respective studies, and each became a luminous and recognised authority. Dr. Smith, when asked in 1869 by Lea Brothers of Philadelphia to write a complete treatise on the diseases of children, at first modestly declined, alleging his unfitness for such a task. Fortunately he afterwards complied, and those who have read his work will long remember the faithfulness of his descriptions and the judgment in his treatment. We do not know any better account of the diarrhœa of children and of the enteritic inflammations to which they so often succumb than is to be found in this book, while the accounts of lesions in fatal cases add much to the scientific value of the records. Dr. Lusk was one of the earliest physicians to appreciate the significance of Lister's antiseptic system and to apply it to the art of midwifery with results that are among the triumphs of medicine in the Victorian era. His text-book is, as we have pointed out year by year in the Student's Number of THE LANCET, one of the best works on the subject in the language. In all parts of his great work, "The Science and Art of Midwifery," there is the same thoroughness of information and display of painstaking investigation, while full accounts of the latest work of other authors give to the work an authoritative character of completeness. Both these physicians have disappeared suddenly from the active spheres of labour and practice. Dr. Smith had been in indifferent health and had sustained two recent accidents which deranged his digestion and enfeebled his heart. He died suddenly from cardiac syncope at the age of seventy. Dr. Lusk also died suddenly, but in his case in the midst of apparent health, cerebral hæmorrhage carrying him off at the early age of fifty-nine years. He laid the foundations of his great medical and obstetrical knowledge in the teachings of Flint and Hamilton in his own country, and supplemented his knowledge by much work in Germany and other European countries. Both Dr. Smith and Dr. Lusk were widowers, but leave children to lament their loss. For further accounts of these interesting careers we refer our readers to our contemporary, the *New York Medical Record*.

THE PATHOLOGY OF CONGENITAL CYANOSIS.

DR. G VARIOT has recently contributed a series of articles to the *Journal de Clinique et de Thérapeutique Infantiles* (May 20th, May 27th, and June 3rd, 1897), in which he disputes the existence of any necessary connexion between cyanosis and congenital malformation of the heart and its great vessels. He quotes two cases which have come under his observation, and which presented almost identical anatomical defects, including marked contraction of the pulmonary artery and deficiency of the interventricular septum. In one of these cyanosis was very evident, in the other it was entirely absent. Dr. Variot is therefore disposed to look to other causes than cardiac malformation for the explanation of this symptom. The theory that it is due merely to admixture of arterial and venous blood, he reminds us, has practically been disproved by the experience of numerous observers. The teaching of the two cases reported by him has naturally strengthened a disbelief in contraction of the pulmonary artery as a sufficient cause, and, as he states, his observation in these instances is not unsupported by that of others. He cannot agree with Dr. Grancher, who attributes congenital cyanosis to causes similar to those which produce this symptom in the adult whose heart is not malformed, and which amount to a species of asystolia with associated disturbance of the whole circulatory system. His own view is that it results from the combined action of morbid change in the red blood corpuscles themselves and of vaso-motor paresis. The crowding together of red blood corpuscles characteristic of cyanotic blood, and already noticed by Gibson, Pierre Marie, and others, was well marked in the two cases above mentioned. It was, no doubt, as the writer observes, most evident in parts liable to vaso-motor action and paresis—the lips, conjunctivæ, &c. He acknowledges, however, the difficulty of deciding whether this crowding is not really attributable to reduction of the hæmoglobin in confirmed and congenital cyanosis as well as in the temporary variety

Digitized by Google

met with in some transient pulmonary disorders. Probably an admission that in mal-aeration of the red corpuscles we have the true cause of cyanosis will best reconcile the writer's theory with the fact that a more or less incompetent heart, whether malformed or not, is usually associated with congenital cyanosis.

THE DANGER OF MIXED COACHES IN A RAILWAY TRAIN.

THE verdict, coupled with a recommendation, of the jury at the conclusion of the inquest on the bodies of the persons who were killed in the accident on the Cambrian railway, near Oswestry, was in the majority of cases published in a short paragraph in a somewhat obscure corner in the daily papers, and its importance may be lost sight of. It raises, however, a very serious question, and we are concerned to know what notice will be taken of it. The jury returned a verdict of "Accidental death," but as to the precise cause of the accident there was not sufficient evidence to show. They added, however, the recommendation that in future four-wheel coaches should not be attached to trains of a modern and much heavier build. Now, this mixing of old with new coaches is constantly going on, especially with cheap excursions trains, and in view of the frequently crowded state of excursion trains proceeding to seaside places and elsewhere it is just these which require more attention in regard to safety than others which run comparatively slow and local journeys. In the evidence given at the inquest referred to, it was shown that the carriages which left the metalswere of the old type. We are sure that this fact has not escaped the attention of the Board of Trade officials, and we hope they will take some steps with a view of preventing the possibility of a similar disaster happening elsewhere.

DARK LIGHT.

THE occurrence of light radiations, be they light, electricity, or other phenomena, which are so rapid in their vibrations as to permeate more or less opaque substances as illustrated in the x rays, has led to a branch of investigation which already has yielded very remarkable results. It is now known that most substances give off an active radiation of some kind when placed in the dark. These radiations are not visible to the eye, but the more sensitive silver film perceives them, so to speak, and, more valuable still, gives a permanent record of them. In the light of recent facts it is really astonishing that the photographer has been able to produce an absolutely unblurred negative. The very cardboard box containing his negatives has been found to produce a distinct effect upon the sensitive film. A piece of polished zinc produces in a similar way a picture of itself, the unevenesses of its surface being portrayed in the truest possible way. This action in no way depends upon contact, since a dividing sheet of celluloid or gelatine may be interposed without interfering with the result, except as might be expected in regard to a little less definition. Paper again transmits these light but yet dark radiations, though glass is apparently an effectual barrier to their passage. This was illustrated in an amusing experiment by Dr. W. J. Russell, F.R.S., who has recently communicated a most interesting paper to the Royal Society on this curious property of a very great number of substances. One of his methods of experimenting was to place the substance—and there is no better emitter of these dark radiations than uranium and its salts—in a pill-box, which he then placed upon a negative in the dark. The fact of a dark circle appearing on the negative showed that the radiations apparently had passed through the cardboard. In this experiment it was noticed that uranium acted more powerfully when in a pill-box than in other ways, and it proved ultimately that the pill-box itself contributed in no small measure to the action on the plate. Strawboard appeared very active, and certain specimens of printer's ink varied in their intensity. This last observation has thrown an interesting light on the resources of some of our esteemed contemporaries. For example, the *Westminster Gazette* is very active (from the point of view of its printing ink, of course), as also are the *Standard* and *Daily Graphic*, but the *Times* is a little less so. The *Evening News* may not be pleased to learn that it is only slightly active, while the *Morning Post*, *Pall Mall Gazette*, *Echo*, and *Daily News* have not the property at all of acting in this way. These differences are due doubtless to variations in the composition of the printers' inks severally employed. The subject is one of peculiar interest, and we may look for results of a still more remarkable kind.

THE ANNUAL DINNER OF THE EPIDEMIOLOGICAL SOCIETY.

ALTHOUGH Friday, June 25th, was the day preceding the Naval Review at Spithead, and thus a somewhat unfortunate date for many, the annual dinner of the Epidemiological Society was better attended than on any previous occasion, and a large number of guests were present. The President (Surgeon-Colonel Lane Notter) was in the chair, and after the usual loyal toasts had been duly honoured, Sir Douglas Galton, K.C.B., proposed "The Army and Navy," a toast which, in the unavoidable absence of the Director-General of the Army Medical Department, was replied to in most happy terms by Brigade-Surgeon Scriven. The toast of "The Visitors" was proposed by Sir Richard Thorne Thorne, K.C.B., who was very cordially congratulated upon his well-deserved Jubilee honour, and was responded to by Dr. Farquharson, M.P., and by Dr. Collins, the Chairman of the London County Council. Sir Walter Foster, M.P., in proposing "The Epidemiological Society," referred to the early history of the society and to the very valuable contributions which it had made to the science of epidemiology during the Victorian era; and the President, in responding to the toast, accentuated the world-wide character of the society, and pointed out that it had its foreign secretaries in all parts of the empire. It would, he trusted, be always the aim of the society to encourage foreign and colonial contributors. The toast of "The Chairman" was proposed by Dr. Whitelegge and duly acknowledged by the President.

A NEW SPECIALTY: RHINO-GYNÆCOLOGY.

TRULY the mysteries of the body are infinite, or is it that the ingenuity of investigators is inexhaustible? Some such reflections cannot but have occurred to our readers last week when they perused the very latest discoveries of "science," as reported from the city that is wont to be regarded as one of the highest seats of medical learning, Vienna. Of course, we are not going to be so bold as to doubt the accuracy of the somewhat singular observations of Dr. Fliess and Dr. Kleinwächter, but we may be pardoned perhaps if we enter a protest against their being made the basis of practice. If we were to name two organs of the human body which have perhaps suffered more than any other from the meddlesome interference of the specialist we should select the nose and the uterus. Instances must occur to the minds of every medical man where these long-suffering regions have been subjected to mechanical violence on grounds that are, to say the least, very insecure. Now, if these Vienna investigators are to be credited, it would appear as if certain

Digitized by Google

disorders of uterine function can be successfully dealt with by a local treatment of the nose! We tremble to think of the perturbation which such a momentous discovery will arouse in the specialistic circle, for who is to decide where the rhinologist shall step in or what are to be the limits of the field of gynæcological operation? In all seriousness we do most earnestly deprecate the practical application of Dr. Fliess's ingenious speculations as being calculated to open the door to an infinite deal of quackery—no other term can be found to indicate such practice—disguised beneath the cloak of so-called science.

SIR JAMES REID, BART., K.C.B.

THE Queen has been pleased, in commemoration of Her Majesty's Diamond Jubilee, to confer the dignity of a Baronetcy upon Sir James Reid, M.D., K.C.B., Resident Physician and Physician in Ordinary to Her Majesty. It is a great pleasure to chronicle this further proof of Her Majesty's high regard for the servant whose personal relations with her are necessarily of the most intimate nature, and we heartily congratulate Sir James Reid upon his well-deserved honour.

THE NEW INFIRMARY AT NEWCASTLE-ON-TYNE.

MR. RILEY LORD deserves the very warmest congratulations. Everyone will remember how about a year ago, when he was the energetic Mayor of Newcastle, he wrote a letter to the public press pointing out the necessity for a new infirmary and urging the fulfilment of the scheme as a fitting memorial of the Diamond Jubilee. Subscriptions flowed in, and the total fund now amounts to the very handsome sum of £100,379 16*s.* 8*d.* This is a result of which Newcastle may well be proud, and the major part of the honours are certainly due to the ex-mayor. We may mention that to finally complete the scheme some £20,000 are still required to be expended on furnishing and sundry other incidental expenses. The number of beds is 400.

"A NON-REGISTERED MEDICAL MAN" AND A "DEATH BY MISADVENTURE."

"I AM a non-registered medical man and not a herbalist. I do not profess any medical or surgical qualification. I am an author and have published five books, one of which is on botany. In that book I tell how one can discover in a minute whether a plant is poisonous or not by examining the bloom. I have travelled in Asia and America. I have practised twenty-four years, fourteen in the house in which I live." Such are the terms in which Mr. Frederick Rawlings, of Willow-grove, Reddish, near Stockport, favours a jury with a little of his interesting autobiography, while giving evidence in a case of injury to the knee which, in the opinion of Mr. G. Passmore, L.R.C.P. Irel., and L.S.A., was one of old injury to the bursa of the patella, and which had been treated by Mr. Rawlings with applications which had set up irritation, followed by absorption of septic material from the inflamed part. The swelling regarded by Mr. Passmore as similar to housemaid's knee was considered by the non-registered medical practitioner as "a tumour" to be broken up and dispersed with irritants, remedies he had used "in over 1000 cases, cases enough to fill the infirmary." We shall not go into the diagnosis of Mr. Rawlings. It is enough to point out that in the judgment of a qualified practitioner Mr. Rawlings's treatment was "bad, wrongful, and ignorant," and that by the coroner and his jury he was let off with a verdict of "Death by misadventure," with this amplification: "The cause of death was septic poisoning from housemaid's knee, and death was caused by misadventure." The coroner carefully instructed the jury that they were not to judge of the case and condemn Mr. Rawlings because he was not a qualified man. We see no reason why the jury should not have done both. It is the privilege of juries and their duty to express free judgments on such lamentable cases where life has been lost for want of proper knowledge and qualification in the attendant. Unless our memory misleads us juries are constantly expressing such judgments to the great advantage and protection of the public. Mr. Rawlings will possibly feel reassured in assuming the airs of a "medical man" and perhaps repeat the treatment which the jury were informed was "bad, wrongful, and ignorant" for twenty years more. What will Mr. Muir McKenzie say with regard to the need for amendment of the Medical Acts in the face of such cases as this?

THE JUBILEE AND THE PUBLIC SAFETY.

DESPITE the appalling prognostications of evil which were so freely made as to the loss of life which would inevitably accrue upon the occasion of the Jubilee, we are happy to say that nothing of the sort occurred. The streets did not fall in under the weight of sightseers; thanks to the admirable inspection of the London County Council no stands collapsed; and, partly owing to the exertions of the police and partly to the common sense of the people themselves, no one was crushed to death in the crowds. The Volunteer Medical Staff Corps, which had some 500 officers and men on duty along the route, report that no serious case occurred under their care. In all 201 cases were attended to, but these were chiefly cases of fainting. In some instances we fancy sightseers followed the example of Mr. Noah Claypole and his amiable wife and pretended to faint, not with the idea of getting brandy during prohibited hours, but so as to get a good place. This was especially the case at the top of Grosvenor-gate, where the St. John Ambulance Society had a station on the refuge in the middle of the road, a place which naturally commanded a good view. The resources of the staff were overtaxed, when some genius suggested removing the station out of sight of the route. After that the epidemic of fainting suddenly ceased. As to the hospitals they had far fewer casualties to treat than on an ordinary day, but all the same, when we think of the possibilities of accident which existed, it is a matter both for congratulation and profound thankfulness that everything passed off so well. Thirty-eight calls to fires were reported to the brigade, in most instances on the line of route of the procession, but none was serious.

MR. W. J. C. MILLER, the lately retired Registrar of the General Medical Council, is, we understand, to be the recipient of a testimonial from some of his friends, contributors to the mathematical columns of the *Educational Times*. His labours on that paper have been carried on for nearly forty years, but the absolute necessity for rest compels him now to resign his interesting and useful work.

THE annual dinner of the Hospital Reform Association will be held at the Holborn Restaurant on Monday, July 26th, at 7.30 P.M., Dr. Ward Cousins presiding. Dr. Ernest Snape, 41, Welbeck-street, London, is acting as honorary secretary, and will be glad to answer all communications. The price of the tickets is fixed at 5*s.* 6*d.*

AT the sixty-third annual general meeting of the Royal Statistical Society, held on June 29th, it was announced that the subject of the essays for the Howard medal, which would be awarded in 1898, with £20 as heretofore, was The Treatment of Habitual Offenders, with special reference to their Increase or Decrease in Various Countries.

HER ROYAL HIGHNESS PRINCESS CHRISTIAN of Schleswig-Holstein will lay the foundation-stone of the new cancer

Digitized by Google

wing of the Middlesex Hospital on Thursday afternoon, July 15th, at 5 P.M.

THERE is no foundation for the statement that Mr. Mayo Robson contemplates resigning his hospital appointment at Leeds and removing to London.

Pharmacology and Therapeutics.

THE ELECTRIC LIGHT IN RHEUMATISM.

DR. KOZLOVSKI, a St. Petersburg physician, publishes in the *Vrach* (No. 14, 1897) an account of his method of treatment of rheumatism and neuralgia by means of exposure to the electric arc. He was induced to make these observations by the statement of Dr. Ewald, who is medical officer to some large ironworks, that he had noticed that since the introduction of the system of electric welding there had been a notable diminution in the number of cases of rheumatism, neuralgia, migraine, and other nervous diseases among the workmen, which he attributed to the beneficial effect of the electric light. In order to bring this therapeutic agent within the reach of ordinary patients Dr. Kozlovski has fitted up consulting-rooms with a suitable plant for producing the electric arc, which consists of a six-horse-power oil engine, a dynamo, thirty-five Tudor accumulators, a rheostat, ampère-meter, and electric arc lamp with reflector. With these he obtains an electromotive force of 50 or 60 volts and a current of from 250 to 300 ampères. The patient is placed at a distance of one and a half metres from the light and protected by blue spectacles and also by a screen of cardboard in which an aperture is cut to allow the light to fall on the affected region of the body. To this it is exposed for from three-quarters of a minute to two minutes. At the time the patient feels a slight sensation of heat, though the temperature is never raised more than 4° F. where the light falls on the skin, but nothing more until six or eight hours afterwards, when itching and tingling are felt and the skin becomes reddened. Some forty-eight hours later desquamation occurs, which lasts for two or three days. In the course of three months Dr. Kozlovski has treated thirty-eight patients, varying in age from thirteen to seventy years, by the electric light. There were eight cases of sciatica, all of which recovered; four of neuritis (locality not stated), two of which recovered; eighteen of chronic rheumatism, fourteen of which recovered; three of lumbago, all of which recovered; three of occipital neuralgia, of which two recovered; and two of trigeminal neuralgia, one of which was greatly benefited. In most cases three or four sittings produced an amelioration of the pain. They were continued at intervals of three or four days, according to the amount of cutaneous irritation, but the total number of sittings never exceeded a dozen.

PICRIC ACID IN ECZEMA.

Picric acid, which, as is now known, is a very useful application in burns, has also been employed with success in eczema by M. Grangé and by Dr. W. Maclennan. In a recent communication to the Paris *Société Médicale des Hôpitaux*, Dr. Gaucher reports very favourably of it. He employs a 1 per cent. solution to paint the affected spots, which he then covers with a compress soaked in the same solution, leaving this on for two days at a time. He finds that the irritation is relieved and that the surface becomes more healthy. This method is applicable only to moist varieties, not to acute or to chronic lichenoid eczemas. He thinks also it would be very suitable in many other moist affections of the skin, such as pemphigus. It should be observed that Dr. Maclennan dealt with acute cases, and employed a saturated solution.

AIROL IN LEPROSY.

An Italian physician, Dr. Fornara, of Taggia, reports a remarkable improvement in a case of typical leprosy of five years' standing, consequent on the use of airol dusted on the ulcers and open abscesses, together with a 10 per cent. vaseline ointment applied to the conjunctivæ and injected into localities where softening had commenced. Tonics were also prescribed and general massage was practised, and at the end of a couple of months the nodules disappeared or diminished considerably in size, the conjunctivæ regained their normal appearance, the hair reappeared, and the cutaneous sensation returned. The drug was well borne, but the gums became discoloured by the bismuth in the airol, and when very large doses were given a certain degree of prostration was observed.

EUCAINE B IN OPHTHALMIC PRACTICE.

According to Dr. Silex, of Professor Schweigger's ophthalmic clinic, Berlin, the so-called eucaine B, which is, of course, closely allied to the older eucaine or eucaine A, has some advantages over the latter as well as over cocaine and tropacocaine—to which it is also closely allied—in ophthalmic practice. First of all, it is very much less toxic than any of these substances. Its hydrochlorate stands boiling much better than that of cocaine, thus rendering sterilisation more simple. The hydrochlorate is soluble in water to the extent of 5 per cent. at ordinary temperatures, and it does not irritate the eye as eucaine A often does. Two drops of a 1 per cent. solution induce in from one to three minutes anæsthesia of the cornea which lasts for a quarter of an hour. In about half the cases examined hyperæmia was observed in the conjunctiva, which, however, did not distress the patients at all, and which was in marked contrast to the anæmia usually caused by cocaine. The pupil was unaffected in diameter, the sphincter reacting promptly; the power of accommodation, too, remained intact. No diminution of tension in the eyeball as sometimes noticed with eucaine A could be detected. In the treatment of foreign bodies in the cornea, corneal ulcers, interstitial keratitis with great irritation, episcleritis and iritis, cocaine appears as suitable as eucaine B; indeed, more so in affections such as iritis in which there is hyperæmia of the anterior half of the eye. In cataract operations eucaine B is perhaps better than cocaine, as it is often of advantage to have a normal pupil during the operation. Six drops of the solution are instilled about ten minutes before the operator is ready. It may be remarked also that eucaine B is cheaper than cocaine, so that in hospital practice it is not unlikely to be preferred in suitable cases.

INJECTIONS OF IODINE IN TUBERCULOSIS.

Campanini gives an account of several cases of Durante's method of treatment in cases of surgical tuberculosis. Two cases of joint disease in which cures were obtained are especially mentioned. In one of these fifty-three and in the other forty-five injections were given, some of which were intra-muscular and some intra-articular. Good results were also obtained in cases of tuberculous glands, especially those which were not associated with any suppurative periadenitis. Lupus, tuberculous orchitis, and epididymitis have all been treated with this method, and two cases of tuberculous peritonitis are also said to have improved under it.

EUCHININ AS A SUBSTITUTE FOR QUININE.

This substance, which is said to have the therapeutical qualities of quinine, occurs in fine white needles which melt at 95° C. and are easily dissolved by alcohol, chloroform, and ether, but dissolve with difficulty in water. It forms salts, of which the muriate is easily soluble in water, while the sulphate and tannate are much less so. The advantages which this drug is said to have over quinine consist in the facts that it is almost tasteless and that it does not produce any headache, noises in the ears, &c., which quinine is apt to do. Clinically it has been used in the same classes of cases in which quinine would be applicable, and it is stated that healthy persons can usually tolerate from fifteen to thirty grains without any ill effects. Chemically the drug is closely allied to quinine, and it is prepared by the action of chlor-ethyl carbonate upon quinine.

LYCETOL AS A SOLVENT OF URIC ACID.

Since the discovery of the all-important part which the presence of uric acid plays in health and disease there has been a constant endeavour to find a drug which will promote excretion of this substance when its presence in the body is causing unpleasant symptoms. One of the last of these solvents is named "lycetol." Lycetol is the tartrate of dimethyl-piperazine, and as such it will be seen that it is closely allied to piperazine, which is also claimed to have a definite solvent action on uric acid. It is a white powder, easily soluble in water, and possessing a pleasant acid taste. The administration of this drug is said to be immediately followed by an increase of the amount of uric acid in the urine, while the actual quantity of the urine is increased and the specific gravity lowered. Dr. R. de Jollenaere reviews the action of this drug in *La Belgique Médicale*, and he considers that without being considered a specific, lycetol none the less must be regarded as a valuable help

Digitized by Google

in the treatment of chronic gout and rheumatism; for under its influence there is often a rapid diminution of pain, accompanied by an increased flow of urine.

AMYLOFORM AND DEXTROFORM.

A new substitute for iodoform has recently been prepared by Professor Classen, of Aix-la-Chapelle, which he names "amyloform," and which consists of a combination of formaldehyde with starch. It occurs as an almost impalpable white powder, devoid of all smell and insoluble in ordinary menstrua. In contact with the tissues of the living body, however, it breaks up, and when it was applied to extensive suppurating wounds formaldehyde could be detected in the purulent discharge. At the same time the urine was proved to be quite free from it by distillation with dilute sulphuric acid and the addition of fuchsin sulphurous acid, so that whatever formaldehyde enters the system must be fully oxidised therein. However much amyloform is applied no toxic symptoms are produced, though a slight and transient smarting sensation is sometimes complained of locally. The clinical effect of the substance is very similar to that of iodoform, only it is frequently more pronounced. In a number of cases of deep wounds with suppuration of bone from osteomyelitis or tubercle a quantity of the powder very liberally applied caused the suppuration to cease in a very short time—in some instances where iodoform had previously been tried without much result. In varicose ulcers of the leg and in the primary sore of syphilis, amyloform also proved useful. The above clinical observations were made by Dr. Bongartz in the Mariahilf Hospital, Aix-la-Chapelle. It has been mentioned that amyloform is insoluble, but a very similar substance has been prepared from dextrin instead of starch, which Professor Classen calls "dextroform," and this is dissolved without much difficulty by both water and glycerine. Its five, ten, or even twenty per cent. solution has proved very useful, as in injection in gonorrhœa, and the two former of these solutions have been employed with success for washing out the cavity of an empyema. Internally the solution has been prescribed with advantage in a case of cystitis.

SICILY
AS A HEALTH RESORT.

III.[1]

Comparative Meteorology and Climatology of Sicily —Contrast between Sicily and (1) Bournemouth, Ventnor, and Torquay; (2) Nice, Mentone, and San Remo; (3) Cairo; and (4) Orotava, Canary Islands.—The Sicilian Flora and its Relation to Climate.—Experiments in Acclimatisation at Palermo.

To complete the survey of the meteorology and climatology of Sicily it will be instructive to institute a comparison between that island and some of the most favourite health resorts of the world. For the purposes of this comparison three of the best-known British resorts will be selected—viz, Bournemouth, Ventnor, and Torquay; three of the best-known Rivieran resorts—viz, Nice, Mentone, and San Remo; Cairo, as representative of the North African sanatoria; and Puerto de Orotava, Teneriffe, as representative of the Canary Islands. It would be easy to enlarge this list, but the exigencies of space place a limit to the range of the survey. As differences, usually slight, but sometimes material, exist in the figures of the meteorological tables furnished by different authorities, it may be well to indicate the writers who have been chiefly relied upon to furnish the data for the following comparisons. For the British resorts "The Climates and Baths of Great Britain," being the report of a committee of the Royal Medical and Chirurgical Society of London, 1895, has been exclusively relied on. For the Riviera the well-known works of Sparks, Marcet, Bennett, and Hassall have been consulted. Sandwith has supplied the figures for Cairo and Samler Brown those for Orotava. The authorities for Sicily have already been fully indicated. Before entering upon the following comparative survey it should be remembered that comparisons between different health-resorts are difficult, and unless made with great caution may be entirely misleading. Climate is a very complex affair, and two sanatoria cannot be fairly compared with regard to one climatological factor without having regard to the others. Thus, if two localities are compared with regard simply to considerations of temperature, the comparison will possess a certain value, but that value will be very limited because the comparison will ignore such vitally important points to the invalid as amount of sunshine, proportion of fine days, amount of rainfall, and character of the prevailing winds. Again, a certain locality may be pre-eminent from one point of view, but quite deficient from another. The island of Monach, in the Hebrides, has one of the most equable climates in the world; but the amount of rain and cloud and the deficiency in sunshine render it useless as a health resort. At Luxor, in Upper Egypt, there is practically no rain, and the sky during winter is usually cloudless; but as a set-off to these great advantages the daily range of temperature is very high and dust-storms from the desert are a serious annoyance. Syracuse has a bright, sunny, equable climate, but the frequency of high winds mars its utility as a health-resort. In fact, as Fonssagrives remarks,[2] "Les climats, comme les caractères, ont les qualités de leurs défauts, et les défauts de leurs qualités." In other words, the value of a health resort must be gauged, not only by its merits, but by its defects and by a judicious appraisement of its *tout ensemble* of meteorological characteristics.

1. *Sicily as compared with the chief British resorts.*—The mean temperature for the whole year at Bournemouth is 49·7° F. (= 9·83° C.); at Catania 64·4° F. (= 18° C.); the mean at Ventnor 50·8° F. (= 10·44° C.); at Palermo 64·6° F. (= 18·1° C.); and at Torquay 49·4° F. (= 9·66° C.). The temperatures for the winter months at the three British resorts and at Catania and Palermo appear in the following table:—

—	Bournemouth.		Ventnor.		Torquay.		Palermo.		Catania.	
	Deg. F.	Deg. C.	Deg. F.	Deg. C.	Deg. F.	Deg. C.	Deg. F.	Deg. C.	Deg. F.	Deg. C.
Nov. ...	45·2	= 7·3	47·8	= 8·7	46·6	= 8·1	60·58	= 15·88	61·05	= 16·14
Dec. ...	39·7	= 4·2	42·3	= 5·7	42·7	= 5·9	54·55	= 12·53	53·76	= 12·09
Jan. ...	39·6	= 4·2	41·6	= 5·3	40·8	= 4·9	51·60	= 10·89	49·51	= 9·73
Feb. ...	39·7	= 4·2	41·9	= 5·5	41·9	= 5·5	52·90	= 11·61	51·67	= 10·93
March ...	41·7	= 5·4	43·1	= 6·2	42·3	= 5·7	56·01	= 13·34	54·52	= 12·51

Dr. Sparks, in his work on "The Riviera," says (p. 2): "On the whole, it may be stated without much want of accuracy that the mean temperature of the Riviera in the winter and spring is from eight to ten degrees higher than that of England." It would appear from the above table that the mean temperature of the Sicilian resorts in the winter and spring is from eleven to fifteen degrees higher than that of England, and consequently from three to five degrees higher than that of the Riviera. The contrast between the British and the Sicilian resorts with regard to the relative humidity of the air is, as might have been expected, great. The figures are as follows:—

Torquay	82·3 per cent.	Saturation = 100 per cent.
Ventnor	81·0 ,,	
Bournemouth ...	77·7 ,,	
Palermo	65·4 ,,	
Catania	61·0	

Not less striking is the contrast between the British and the Sicilian resorts as regards the proportion of rainy days in the year. The following are the figures: Torquay, 187 rainy days per annum; Ventnor, 164; Bournemouth, 158·3; Palermo, 116; and Catania, 86.

The returns from the British resorts do not state the number of days of frost, fog, or high winds, so that any comparison under these heads is impossible. It may, however, be borne in mind with advantage that at Palermo the thermometer touches freezing point about two or three times

[1] Nos. I. and II. were published in THE LANCET of June 5th and 12th, 1897, respectively.

[2] Article, Climat, in the Dictionnaire Encyclopédique des Sciences Médicales, Paris, 1878.

Digitized by Google

in the year, at Catania rather less frequently, and that at both resorts fog is practically unknown. In these respects the superiority of the Sicilian resorts is, as might be expected, very decided. The mean daily range of temperature is not given in all the English returns, but it is stated to be only 10·6° at Ventnor, which is rather under the Sicilian average. To sum up, while the British resorts present considerable advantages to patients who are unwilling to face a long journey and expatriation, they are inferior to the Sicilian resorts as regards the general warmth and brightness of the invalid season, the number of rainy days, the amount of cold, frost, and fog; in fact, in most of the essential meteorological features for which the invalid usually seeks climatic change.

2. *Sicily as compared with the chief Rivieran resorts*.—The following is the comparison as regards the mean temperature for the winter and spring months:—

—	Nice.		Mentone.		San Remo.		Palermo.		Catania.	
	Deg. F.	Deg. C.	Deg. F.	Deg. C.	Deg. F.	Deg. C.	Deg. F.	Deg. C.	Deg. F.	Deg. C.
Nov. ...	53·8 =	12·1	54·1 =	12·3	53 54 =	11·9	60 58 =	15 8	61 C5 =	16 1
Dec. ...	48 5 =	9·1	49 7 =	9 8	49 25 =	9·5	54·55 =	12 5	53·76 =	12 1
Jan. ...	47·0 =	8·3	49·0 =	9 4	47·23 =	8·4	51·60 =	10·9	49·51 =	9 7
Feb. ...	48·4 =	9·1	48 6 =	9·2	50·19 =	10·1	52·90 =	11 6	52·67 =	10·9
March ...	51·8 =	11·0	50·7 =	10 4	52·0 =	11·1	56 01 =	13·3	54·52 =	12·5

The higher rate of warmth at the Sicilian resorts during the winter and spring months is thus evident. The number of times that the thermometer touches freezing point in the course of the winter is one convenient gauge of the mildness or severity of the climate. The data for an exact comparison under this head are not available, but the existing evidence would appear to indicate that freezing point is touched much more frequently at Nice, Mentone, and San Remo than at Palermo or Catania. It must also be borne in mind that any considerable degree of cold is unknown in Sicily at the sea level, but well known, although exceptional, at the Rivieran resorts. As regards the relative humidity of the air the figure for Nice—viz., 59·6 (mean of observations taken at 2 P.M.)—may be compared with that of Palermo—viz., 65·4, and for Catania 61 per cent. No one familiar with the Riviera and with Sicily can doubt for a moment that the air of the former is drier than that of the latter, but it would appear from these figures that the difference is considerably less than might have been supposed. If, in accordance with the views of most writers on the subject, the climate of the Riviera be regarded as dry, then the climate of Sicily cannot be called damp, the difference in relative humidity being really small. The Rivieran resorts show very favourably with regard to that which is their chief glory, viz, their remarkably high proportion of fine days and low proportion of wet and cloudy days. The number of rainy days per annum at Nice is 70; at Mentone 80; at San Remo 48; at Palermo 116; and at Catania 86. Here, therefore, is an important point, in which the Rivieran climate has a superiority over the Sicilian, though it will be noticed that Catania is but little below the average of Mentone. Indeed, Professor Ughetti[3] claims an actual superiority for Catania as regards serenity of sky and proportion of fine weather. He quotes the following statements from Schivardi: "From Nov. 1st to March 30th Mentone has on an average 50 days of rain, Catania only 26. From Oct. 1st to April 30th San Remo has 83 days of cloudless sunshine, as compared with 103 at Catania, 95 'mixed' days (days of partial cloud and partial sunshine), as compared with 76 at Catania, and 34 rainy days as compared with 33 at Catania." Readers have probably already appreciated the extreme difficulty of obtaining absolutely precise data with regard to meteorological details. These figures must be allowed to speak for themselves. It appears probable that while Sicily as a whole is inferior to the Riviera in the proportion of fine weather, Catania and its neighbourhood are practically on a par with Mentone and San Remo. It will be found that in the matter of winds sunny Sicily has a decided advantage over the sunny Riviera. It is admitted by every competent authority that cold winds are the grand drawback to the otherwise admirable climate of the Riviera. The old saw remains true as regards the mistral—

> "La Cour de Parlement, le Mistral et la Durance
> Sont les trois fléaux de la Provence."

Much heated argumentation has taken place regarding the

Syracuse from the Sea-front.

[3] Vide L'Inverno a Catania, by Dottor G. B. Ughetti.

Digitized by Google

frequency of the mistral, its varying rates of virulence at the different Rivieran resorts, &c. Without touching upon ground that is in any way disputable, it may fairly be assumed that the mistral is somewhat frequent on the Riviera, that it is both disagreeable and dangerous, and that it constitutes a serious objection to the climate. Now, broadly speaking, cold winds are unknown in Sicily, the tramontana and greco being very rarely disagreeable to the healthy individual or hurtful to the invalid. The chief drawback, however, to the Sicilian, as to the Rivieran, climate is a wind, but in the case of Sicily it is a hot, not a cold wind—viz., the sirocco, and, moreover, a wind which, though highly disagreeable, is not injurious to health, and which is, as a rule, better borne by the ailing than the healthy. Summing up, it may be said that the climate of Sicily is warmer, more equable, and more free from extremes than that of the Riviera; that in dryness of the atmosphere and average of fine sunny weather the Riviera has a slight, but only a slight, advantage; and that the hot winds of Sicily are less frequent during the invalid season and less perilous to health than the cold winds of the Riviera.

3. *Sicily as compared with Cairo.*—The contrast of mean monthly temperatures is as follows:—

—	Cairo.	Palermo.	Catania.
	Deg. F. Deg. C.	Deg. F. Deg. C.	Deg. F. Deg. C.
November	64·4 = 18·0	60·58 = 15·8	61·05 = 16·1
December	58 4 = 14·6	54·55 = 12·5	53·76 = 12·1
January	53·3 = 12·0	51·60 = 10·8	49·51 = 9·7
February	57·0 = 13·9	52·90 = 11·6	51·67 = 10·9
March	62·8 = 17·1	56·01 = 13·3	54·52 = 12·5

It will thus be seen that Cairo is about as much warmer than the Sicilian resorts as they in their turn are warmer than the Rivieran resorts. The minimum temperature recorded at Cairo during the winter is usually about 35° or 36° F. (= 2° C.), and freezing-point seems never to be reached (Sandwith). The mean daily range of temperature at Cairo is great. According to Marcet, the mean temperature at Cairo during the winter season at 3 15 o'clock P M (the hottest time) varies from 79 2° F. (= 26 2° C.) to 83 7° F. (= 28 8° C), and the mean temperature at 3 15 o'clock A.M. (the coldest time) varies from 38 7° F. (= 3·7° C.) to 39 9° F. (= 4 4° C.). Here there is a striking contrast to the mean daily range of Sicily, which may be taken as about 12° F. or 13° F., recalling the cardinal defect of the Egyptian climate —viz., its lack of equability. The mean relative humidity of the air at Cairo is 58·4 per cent., which may be compared with the rate at Palermo (viz., 65·4 per cent.) and that at Catania—viz., 61 per cent. A greater contrast would have been expected under this head, but the remark of Sandwith may be recalled: "Although Cairo is exceptionally dry it has its damp moods at times, and several times a year for a few hours reaches saturation on the humidity scale." As regards average of fine weather, Cairo, as might be expected, far surpasses any of the European resorts. Cairo has an average annual rainfall of 1·22 in., and the average number of rainy days per annum is about 12 or 13. Cold winds are not, as a rule, frequent or dangerous in Egypt, but the khamseen wind, blowing from the south or south-south-east, is in many respects comparable to the sirocco of Sicily. It is evident that the climates of Cairo and of Sicily present points both of analogy and contrast. Both have a high proportion of sunshine and fine weather, but in this respect Cairo has much the advantage. Cairo has a dry climate—Sicily a climate of medium humidity. Cairo has a very high daily range of temperature—Sicily a moderate daily range. Both suffer from winds, but from hot, rather than from cold, winds. Both are somewhat dusty places, but this inconvenience and danger is much greater in Egypt than in Sicily.

4. *Sicily as compared with Orotava (Canary Islands).*—The contrast between Sicily and the Canary Islands is in many respects one of peculiar interest, and it is a matter of regret that fuller meteorological tables are not available for the Canary Islands. These islands are situated in 28° and 29° N. latitude, or about 8° or 9° nearer the Equator than Sicily, but the resemblance, meteorological and botanical, between them and Sicily is closer than their relative geographical position would suggest, the explanation, no doubt, being that both feel the influence of the neighbouring African continent.

The contrast of mean monthly temperatures is as follows:—

—	Orotava.	Palermo.	Catania.
	Deg. F. Deg. C.	Deg. F. Deg. C.	Deg. F. Deg. C.
November	64·7 = 18·1	60·58 = 15·8	61·05 = 16·1
December	61·2 = 16·2	54·55 = 12·5	53·76 = 12·1
January	59·6 = 15·3	51·60 = 10·8	49·51 = 9·7
February	60·4 = 15·7	52·90 = 11·6	51·67 = 10·9
March	62·0 = 16·6	56·01 = 13·3	54·52 = 12·5

Orotava is thus seen to be appreciably warmer in winter and spring even than Cairo. The mean daily range of temperature at Orotava during the season is stated to be 13°F., which is very near the Sicilian average. The relative humidity of the air at Orotava is high—viz., 75 per cent.—the climate being thus somewhat damp. The number of rainy days from November to March (inclusive) is about forty, and although there is a considerable amount of cloud the proportion of fine weather and sunshine is high. The analogy between the Canary Islands and Sicily is, on the whole, close, and when the subject of the Sicilian flora is dealt with it will be found that the meteorological resemblance of the two localities is illustrated by the affinity presented by their respective plant life. The chief points of difference appear to be that Orotava is somewhat warmer and damper than Sicily. Considerations of space prevent the analogy between Sicily and the Canary Islands being pursued, and the differences—not unimportant—between Oratava and Santa Cruz and Las Palmas cannot be entered into. The first has been selected as representative of the group of islands because, on the whole, it is the best known and most frequented.

The final outcome of the above comparisons is to illustrate once more the intermediate character of the Sicilian climate —intermediate in meteorological features, intermediate also between Europe and Africa. In Sicily the climate is (during the winter and spring) free from extremes of heat and cold, of medium humidity, decidedly equable on the whole, but showing a fair mean daily range of temperature, possessing a very high average of sunshine and fine weather, practically free from mist and fog, and without any serious drawback, except the sirocco, which is at its minimum during the invalid season. It would seem probable that a climate possessing so much of the "aurea mediocritas" should prove somewhat widely applicable to cases of debility and disease. Before entering upon this question, however, the survey of the subject will be completed by dealing with the exceptionally interesting topic of the Sicilian flora. The following facts are given on the authority of Professor Borzì, Director of the Orto Botanico of Palermo.

The flora of the Conca d'Oro of Palermo is one of the richest and most varied in the world, and attempts at acclimatisation of tropical and sub-tropical plants have been remarkably successful. Warmth and equability of temperature, a considerable rainfall, almost complete freedom from frost or severe cold, and a fair degree of shelter combine to make Palermo the paradise of the botanist. In few places can so many plants belonging to widely-separated regions of the world be found flourishing side by side, and apparently finding in soil and climate every condition necessary for their growth and maturity. Among the foreign species which flourish at Palermo may be mentioned those of the Canary Islands, Northern Africa, Asia Minor, Eastern Hindostan, Java, Australia, Cape of Good Hope, Madagascar, East Africa, Mexico, California, and Brazil. Nearly every variety of ficus comes to maturity here in the open air, also the agave, the arborescent forms of the liliaceæ, and, with a few exceptions, nearly all the cicadaceæ and the musaceæ. As instances of purely tropical plants which have been successfully cultivated in the Orto Botanico of Palermo may be mentioned the following: the Archontophœnix Alexandræ of Australia, the Ficus religiosa of Eastern Hindostan, the Quisqualis indica of Tropical Asia, the Grevillea Hilliana of Australia, the Banhinia acuminata of Malacca, and the Doryanthes excelsa of Australia. Botanists will appreciate the significance of this list, which might be indefinitely enlarged. Highly interesting and important also are Professor Borzì's observations regarding the period of flowering of plants in the

Digitized by Google

Orto Botanico. This, it need hardly be remarked, is perhaps the most delicate test of climate, and one absolutely free from every possible source of error that can be devised. Professor Borzì finds that in January (with a mean temperature of 51·6° F. = 10·8° C.) the following plants come into blossom—viz., the Abutilon Thompsoni, the Aloe arborescens, the Bougainvillea aurantiaca, the Euphorbia fulgens, the Strelitzia reginæ, the Aechmea Lindeni, the Albizzia lophantha, the Dombeya ferruginea, the Tecoma capensis, the Impatiens Sultani, the Nicotiana tabacum, and the Spermannia africana. In the month of February (with a mean temperature of 52·90° F., = 11·6° C.) the following plants come into flower—viz., the Abutilon hirtum, the Acacia longifolia, the Guarea coffeæfolia, the Rhaphiolepis indica, the Tropæolum tricolorum, the Cycas revoluta, and the Erythrina viarum. In March (with a mean temperature of 56·01° F.) the following plants come into flower—viz., the Cercis Siliquastrum, the Heliotropium peruvianum, the Livistona australis, the Mesembryanthemum acinaciforme, the Bignonia floribunda, the Chorizema cordatum, the Rondeletia Roezlii, the Begonia ricinifolia, the Eucalyptus amygdalina, the Pelargonium Radula, the Physalis peruviana, the Pæonia moutan, and the Staphylea colchica. The above are selected as some of the most striking examples from a list which contains a much larger number of plants. They amply justify Professor Borzì's allusion to "il rigoglio della vegetazione qui"—i.e., in Palermo—"mentre altrove, in eguali latitudini, la natura è morta o quasi" (the luxuriant growth of vegetation here at a time when in other localities in the same latitude nature is practically dead). Palermo is not less notable for the number and variety of the fruits which there attain maturity. The pineapple (Ananas sativus) ripens without artificial heat, merely demanding shelter. In the open air, without artificial heat or special protection, grow the banana, the monstera, the guava, the anona, the kaki, the eugenia, and the sugar cane. Many species of bamboo, nearly all the agave, and the sanzeviere come to full maturity, cotton grows freely, and the coffee plant, if protected from the winds, brings forth good and aromatic fruit. It need hardly be said that oranges, lemons, figs, and almonds are among the most ordinary fruits abundantly produced upon the Conca d'Oro. This remarkable adaptability of the climate and soil of Palermo to the plant life of the most diverse localities has induced Professor Borzì to make the suggestion that the Sicilian capital should be made the seat of an International Acclimatisation Garden, where botanists from different countries might study the flora of many different regions simultaneously and enjoy the full advantages of the comparative method of observation. He is of opinion that "without excessive or extraordinary care the greater part of the representatives of the tropical flora could be freely cultivated in Sicily." There can be no doubt of the correctness of this opinion, and Professor Borzì's project will have the hearty approval of the scientific world.

The above botanical data bring into strong relief the mildness of the Sicilian climate and its almost semi-tropical character. Bennett, in his well-known work, "Winter and Spring on the Shores of the Mediterranean," makes the statement (p. 416) that "the more southern latitude of Palermo, without mountain protection from the north, gives it as warm a winter climate as the Riviera enjoys with protection from the north, but not a warmer one. The two regions seem to be singularly identical, considering the distance that separates them, as regards the character of their vegetation and its development." The above statements are decidedly erroneous. The winter climate of Sicily is on an average from 3° to 5° F. warmer than that of the Riviera, and the Sicilian flora is much more varied and more sub-tropical than the Rivieran. The wild flowers of Sicily are among the most varied and most beautiful in the world. Although many parts of the once fertile and luxuriant interior of the island are now bare and barren, there are other parts where the hillsides are ablaze with mesembryanthemums and marigolds, lupins, and cornflowers. On the slopes of the higher mountains a great variety of plant and tree may be observed. On Etna three zones are distinguished. First, a lower zone, extending from the sea level to an altitude of 1400 metres. Here grow abundantly olives, oranges, lemons, almonds, figs, pomegranates, vines, apples, pears, &c. This district is described, perhaps with a slight touch of Southern exaggeration, as "la regione più fertile e deliziosa d'Europa" (the most fertile and delicious region in Europe). The second zone ("Boschiva") extends from 1400 metres to 2200 metres of altitude. Here grow the oak, castagna, birch, beech, and various pines. The third zone ("Deserta" or "Scoperta") extends from the limit of the second zone to the summit. The flora is scanty and alpine in character.

The evidence—meteorological and botanical—upon which judgment regarding the general character of the Sicilian climate must be based has now been sufficiently indicated. It remains to inquire what is the general effect of the climate upon the human organism in health and disease—i.e., what is the medical climatology of Sicily. The terms which have to be employed in this connexion leave much to be desired in point of scientific precision, although in a popular way their meaning is clear enough. A climate is *tonic* if it tends to promote digestive vigour and vascular tone. If it has the contrary effect it is *relaxing*. A climate that tends to heighten the activity of the nervous system may be called *stimulating* or *exciting*, while a contrary tendency is called *sedative* or *depressing*. The term *bracing*, which is so often used, would seem to imply that the climate thus designated is both tonic and stimulating. These vague and quasi-popular expressions must be employed because there are literally no others available. The climate of Sicily may be most correctly described as (*a*) *moderately tonic*, and (*b*) *sedative*. It is moderately tonic by virtue of its high proportion of sunshine and fine weather and its general breeziness. It is sedative by virtue of its medium degree of humidity and its equability of temperature. It is often said that the Sicilian climate is relaxing, and it may be admitted that the statement may be true as regards certain localities, certain seasons, and certain individuals, but if put broadly the statement is erroneous. A climate with a relative humidity of only from 61 to 65 per cent., with a very high average of sunshine and cloudless skies, and with a pretty constant though moderate atmospheric movement, could not be relaxing in its main effect. That the climate may be correctly designated as moderately tonic is further demonstrated by the fact that it is found to suit very well in diseases that call especially for tonic influences—viz., tuberculous and glandular affections generally. The sedative influence of the climate upon the nervous system is admitted by all observers, and is, indeed, quite manifest. Nervous irritability is reduced by the soft, soothing, and equable Sicilian air. Sleep improves and excitement subsides. Hence, speaking generally, conditions associated with irritability, such as some forms of neurasthenia, some varieties of asthma, spasmodic laryngeal affections, &c., do well in Sicily.

Though the differences from the point of view of medical climatology between the various Sicilian localities cannot be called great they are quite appreciable. The climate of Palermo is less tonic and more sedative than the climate of Catania and *vice versâ*. Taormina represents one of the most tonic climates in Sicily—i.e., among localities at present available to tourists or invalids—the Conca d'Oro, one of the most sedative, while Girgenti is probably intermediate. When the diseases for which the climate of Sicily is specially suitable are considered in detail it will be found that the problem may be usually stated in this form—What are the morbid conditions likely to be benefited in a climate which, on the whole, promotes digestion and sanguification, and which is moderately soothing to the nervous system? The discussion of this question will be reserved for a future article.

WITH THE PUNITIVE EXPEDITION TO BENIN CITY.

BY R. ALLMAN, L.R.C.P. IREL., &C.,
PRINCIPAL MEDICAL OFFICER, NIGER COAST PROTECTORATE.

THE capture of Benin City and the events which led to it are too well known to need recapitulation, but perhaps a brief account of what occurred there subsequently to the occupation may be of some interest. The city was occupied on the evening of Feb. 18th by the expeditionary force, all of whom, especially the Europeans, were well-nigh worn out by the time the camp was reached. This is not to be wondered at when it is considered that on the final day we had to fight our way through dense bush for nine consecutive hours without any water to drink. I need

Digitized by Google

hardly say that very little interest was taken in anything for the remainder of that day, except for the safety of the camp and the care of the sick and wounded, everyone seeming to rest on his oars now that the goal had been reached. As this was the first good night's rest we had had since leaving Ologbo (five days before) it is needless to say that it was appreciated by all. Early next morning (Feb. 19th) a burial party, composed of bluejackets and marines, were told off to bury their dead messmates who had fallen on the previous day. Having disposed of these our next care was to ensure by sanitation of the city the health of the living. This proved a more formidable and offensive undertaking than I had at first imagined, as the city positively reeked with blood and the atmosphere was impregnated with the stench of decomposing human sacrifices, &c. However, there was no alternative but to dispose of the bodies in the quickest manner possible, as the polluted atmosphere had already affected the Europeans and the native troops and carriers; six of the latter died from an acute type of dysenteric diarrhœa, the Europeans suffering from a similar disorder—so between cremation and burials I disposed of upwards of six hundred human corpses. On Sunday, Feb. 21st, a fire broke out in the south-west corner of the city consuming the greater portion of it; owing to the rapidity with which it spread many of us lost nearly all our personal effects. However, it had a most salutary effect in cleansing the polluted atmosphere, a marked improvement being at once observed in the general health.

To convey some idea of the number of crucifixions and sacrifices witnessed in this "city of blood" it will be necessary to enter into a few gruesome details. Facing the principal entrance to the King's compounds stood a large sacrificial tree on which two bodies were crucified, and scattered in all directions around its base lay numbers of decapitated and disembowelled sacrifices in various stages of decomposition, amongst which were the decapitated remains of three Europeans, who had evidently been gagged and their hands bound behind their back before execution. A few hundred yards to the south of the main entrance, already alluded to, stood another sacrificial tree, on which was crucified the body of a woman, and at its base three other eviscerated bodies (also women) were found. Continuing my way to the south I came upon the large plain leading to the Gwato Path, and there witnessed one of the most horrible sights that it is possible for the human mind to conceive—i.e., one hundred and seventy-six newly decapitated and mutilated human sacrifices strewn about in all directions, besides countless numbers of skeletons—truly, a most gruesome sight and one not to be easily forgotten.

I will not describe any more of these horrible details; suffice it to say that sacrifices were found in nearly every portion of the city, some of the bodies being most brutally and cruelly mutilated. Before closing this tale of blood I may, however, give a brief sketch of the huge pits (seventeen in number) found principally in the vicinity of the regal palace. These pits were of enormous dimensions—12 feet in diameter and 40 feet deep. Seven of these contained human sacrifices (from fifteen to twenty in each pit); out of these "foulsome pits" (the stench emitted being intolerable) we rescued with great difficulty seven unfortunate captives, who for several days afterwards could hardly realise what had happened; two of them were carriers on Mr. Phillips's ill-fated expedition.

To change the subject to something more interesting and pleasant I shall endeavour to give a brief account of the Benin capital, its inhabitants and industries. Benin City is a large, straggling, walled-in town of about 20,000 inhabitants, and covers an area of about two square miles; it is situated on a plateau 176 feet above the sea level. The wall surrounding the city is in many places twenty feet high with a base four feet wide, which gradually tapers off to eighteen inches at the top. Judging from its solidity I can well imagine how perfectly secure the inhabitants felt from the raids or weapons of the surrounding tribes; coupling this with the strong belief in their fetiches, it is no wonder they considered themselves invincible. The first things that strike the observer on entering the city are the large walled in compounds, 200 yards square, met with in all the principal quarters of the city; through four of these one has to pass before reaching the King's palace and Palaver house. At one end of each compound stands an altar decorated with large bronzes and enormous carved ivory tusks, the whole being smeared and crusted over with human blood; these altars (seventeen in number) I afterwards learnt from the chiefs who submitted to the Government were the shrines of the defunct kings of Benin. The antiquity of each could easily be traced by the appearance and condition of the carved ivories which decorated them; the most recent one was evidently only in existence about nine years, and it was at this shrine that Duboah the king was making sacrifices to the shades of his father when Mr. Phillips and his ill-fated party sought the interview with him.

The mode in which sacrifices were conducted at these shrines is simple in the extreme. The unfortunate victim is placed on the altar and knocked on the head with a sacrificial club (with which each altar is supplied), and then cast, whether dead or alive, into one of the large pits already mentioned.

The dwelling houses, especially those of the king's harem, were beautifully built and tastefully decorated throughout, some of the mud seats and couches being artistically inlaid with cowries, which had a most pleasing effect. The king's palace and palaver houses were most substantial buildings with metal roofs (yellow metal). Huge bronze snakes were represented wriggling on the roof of the latter with heads downward—in fact, on all their manufactured articles and carvings this reptile is freely displayed, it being their emblem of sovereignty, subtle and treacherous.

From what I saw of the Benin tribe I certainly consider them splendid specimens of the negro race—tall, of fine physique, and not wanting in intelligence, as their industries and arts go to prove. I was not able to learn much about their customs and habits during my stay in the city (five weeks), as they only commenced coming in in numbers on April 17th to tender their submission, one month after the capture of the city. Their chief industries, as far as I could learn, were moulding in bronze, carving on ivory, and blacksmiths' work generally, at all of which they are most skilful and proficient. Some of the bronzes are beautifully designed, moulded, and cast, and the carvings in ivory and wood are most wonderfully contrived and executed. In my wanderings about the city I came across many bronzes and plaques which were evidently designed, if not executed, by the ancient Egyptians; many others were of more modern times and bore traces of the Portuguese, from whom the art has without doubt descended. Amongst others I picked up a bronze figure of our crucified Saviour; this, with other emblems of Christianity found in the city, led me to believe that the custom of human crucifixions as practised by the natives was derived from the representations of the Crucifixion of our Saviour introduced, probably, by the Portuguese. The manufacture of bronzes was evidently carried on under the direct supervision of the kings, as the smelting pots and the clay and beeswax for moulding, &c., were all arranged in a compound adjacent to the palace. Several moulds in various stages of completion were found here; those ready for casting presented when broken the following appearance. A mould of special clay formed the base, over this a likeness of what was required was beautifully modelled in beeswax, and outside this a covering of "potter's clay," the whole being enwrapped in ordinary mud or mortar. I can only conjecture the final process to complete the operation—i.e., the mould, after being sufficiently sun-dried, is transferred to the smelting pot and completely submerged in the molten metal, which takes the place of the wax, and the object is accomplished. Under the able administration of Mr. R. Moor, H.M. Commissioner and Consul-General, there is a great future in store for this lately acquired territory.

Old Calabar.

"A WATER FAMINE IN SOUTH LONDON."

UNDER the above heading the following letter appeared in the *Times* of June 26th:—

"SIR,—Allow me, if you please, to call public attention to the sufferings which are now being endured by a large area of the suburban population—how large I am not able to say—by reason of the non-supply of water by the Lambeth Waterworks Company.

"On Monday not a drop of water came into this house. On Tuesday enough came in just to fill the cistern and no more. On Wednesday the same. To-day not a single drop. Meanwhile the misery we are enduring is indescribable. Horses and dogs are suffering, our sanitary arrangements are in a terrible condition, our drains are unflushed, the luxury of a bath is denied to us, and we live in constant terror of a blow-up in the kitchen.

"I have bombarded the company with letters and telegrams worded as strongly as I could, but, till this morning, with no result beyond the stereotyped printed form acknowledging receipt of my communication, 'which shall receive attention.' Now at last cometh a

Digitized by Google

letter from the engineer of the company condescending to inform me—on this the fourth day of the water famine—that the failure of the supply has been due to a breakdown at the Ditton Works which the company 'could not advise consumers of, owing to the fact that we had no forewarning of the occurrence and to the large area affected.'

"Comment on the above is hardly necessary. That such a 'breakdown' should be possible is simply unpardonable. If, as must be the case, for there has been no drought or drying up at the fountain head, the pumping machinery has gone wrong, can there be any excuse whatever for the power not being in duplicate so that the risk of such a frightful stoppage of supply would be at least halved?'

"*An attendant*, with the thermometer standing at 80 deg. in the shade, we are waiting in vain for the welcome inrush into the cistern of the element for which we have paid, and without which we must soon perish. "I am, your obedient servant,

"137, High-street, Sydenham, S.E., June 24th." "A. C. ANDROS.

We have thought the matter of sufficient importance to re-publish this letter *in extenso*. It will be seen that the statements of the correspondent are perfectly definite. The points of interest are that on Monday, June 21st, "not a drop of water" went into the house No. 137, High Street, Sydenham; on Tuesday, June 22nd, only an amount of water "sufficient to fill the cistern" was received; on Wednesday, June 23rd, again only enough water arrived to fill the cistern; on Thursday, June 24th, at the time at which the letter was written no water had been supplied. The hour at which the letter was written is not, however, given. These statements are precise and definite, and they require explanation. The correspondent says that he has received a letter from the engineer of the Lambeth Waterworks Company, and he gives a quotation from it. The engineer said that they could not tell their customers that the water-supply would be deficient—firstly, because they had no "forewarning of the occurrence"; and secondly, because "the area affected was a large one." The statement of the engineer that the area affected was a large one is of considerable interest, and we should be glad to know how many people besides the correspondent who wrote to the *Times* suffered from a deficiency or absence of water-supply. On Monday, June 28th, a letter was published in the *Times* from Mr. H. Wilkins, secretary to the Lambeth Waterworks Company. The letter is as follows:—

"SIR,—With reference to the letter from Mr. A. C. Andros in your issue of to-day under the above heading, will you allow me to say that the normal supply of water was resumed throughout the company's district on Thursday, the date of Mr. Andros's letter, although it is quite possible that the full pressure was not felt at some of the higher levels until the following day? The pumping machinery is in duplicate. The difficulty was with some of our filter beds.

"The average daily supply for the year is about 23,000,000 gallons, and the average for the present week exceeds this quantity. On no day have less than 20,000,000 gallons been sent into the district. Whether the term 'water famine' is fitly applied to such a condition I leave your readers to judge. Probably no inconvenience whatever would have been felt but for the sudden accession of hot weather.

"I need scarcely say that the company extremely regret the occurrence, which, however, was due to causes entirely beyond their control. May I add a word of thanks to our consumers generally, who have been good enough to submit to temporary inconvenience without unreasonable complaint? "I am, Sir, your obedient servant,

"H. WILKINS, Secretary.

"Lambeth Waterworks, Brixton-hill, S.W., June 26th."

It will be noticed that the secretary of the Lambeth Waterworks Company does not deny any of the statements made in the letter of Mr. Andros. We may, therefore, assume that the statements made as to the deficiency or absence of the regular water-supply at No. 137, High-street, Sydenham, existed from Monday, June 21st, up to Thursday, June 24th. We may further assume that the quotation which Mr. Andros gives from the letter which the engineer of the company sent to him is also correct, and that the area affected by the water famine was a large one. The secretary of the company in his letter to the *Times* is not explicit as to the cause of the deficiency of the water-supply. What he does say on the matter is, firstly, that the difficulty was with some of the filter beds; and, secondly, that it was due to causes entirely beyond their control. We do not consider this explanation either ample or satisfactory, and we await further information with interest.

MEDICAL MAGISTRATES. — Mr. Edmund J. Thompson, M.R.C.S. Eng., of Measham, Atherstone, and Mr. William Holder, M.R.C.S. Eng., of Hull, have been placed on the Commission of the Peace for the county of Derby and the city of Hull respectively.—The following gentlemen have been appointed magistrates for their respective colonies—namely, Mr. J. L. M. McCreadie, M.B. Syd., of Gulong, New South Wales; Mr. A. Philip, L.K.Q.C.P., L.R.C.S. Irel., of Surry Hills, Sydney, New South Wales; and Mr. S. S. Richards, M.B., Ch.M. Syd., of Mount Morgan, Queensland.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Enteric fever in the town of Bicester, by Dr. THEODORE THOMSON.[1]—The report presented to the Local Government Board by Dr. Theodore Thomson on this occurrence of enteric fever contains many points of interest. In the first place, it is stated that when the inquiry was ordered no report on the outbreak had been received as to it from the medical officer of health, in accordance with the terms of the order of the Local Government Board. We refer to this because we so often read a similar statement; and this failure to report seems to be one of the most certain methods of bringing about a visit of a medical inspector. In this instance that visit can only have done good, and hence no one really interested in the health of the town can regret it. The story is a very excellent one from the etiological point of view. Bicester had a by no means good record as to enteric fever, and a few years ago there were 56 cases. Odd cases occurred in the early summer of 1895, then came a group of "suspicious" cases, which were obviously, in the main, genuine cases unrecognised; then followed a batch of 28 notifications in four weeks, and a very painstaking research ultimately identified nearly every attack with the use of water from a somewhat famed spring well; indeed, the disease picked out people who used this water even at a distance from the well, near which the great incidence of the disease fell. The well was closed. Then ensued another batch of 10 cases, still in the same portion of the town, and these were connected with the use of water from a second well; and, lastly, came another batch of 11 cases, obviously associated with the use of water from a third well close by the infected area. As already implied, the disease was practically restricted to one portion of the town; and it was quite clear that the houses infected had nothing in common but a polluted water-supply which had opportunities of receiving specific contamination. The first water-supply which became infected after the occurrence of isolated attacks of enteric fever was so contrived that it could not escape sewage contamination. It was situated in a sort of angle formed by two sewers, and the angle was so arranged as to allow the contents to exude and to infiltrate the surrounding soil in the most efficient manner that could be devised. Sunk in the pervious calcareous sandstones of the cornbrash, all was ready for precisely that which did happen. But this was not the only leaky point in the Bicester sewers, which were now getting specifically polluted; and other wells soon followed suit in spreading the disease. Into one of these a drain was found to be visibly percolating, and a third was close to a public-house urinal. In fact, these wells are sunk in pervious strata, which, by reason of negligent sanitary work and still more negligent sanitary administration, have been allowed to become infiltrated with filth; and when periodically the filth is derived from specifically diseased excreta—as doubtless in 1890, and certainly in 1895–96—there follows an outbreak of disease. It must not be assumed that the local authority were ignorant of this state of affairs, for in 1890 Mr. Dyson Wood, their medical officer of health, told them that "a safe water-supply for the district is essential." The effect of this decided advice is seen in the epidemic to which Dr. Thomson's report relates. It was practically ignored. And worse, in October, 1895, when the disease was in full force, the sewer near the implicated well was found "to be leaking freely into the surrounding soil at several points"; but in April, 1896, Dr. Thomson found that these conditions "remained unaltered." So, also, the progress of the enteric fever and of the death it occasioned remained practically unaltered, for other wells soon received the specific pollution; the disease went on in two further batches up to Jan. 4th, and again by the end of March 9 more cases had been recorded, making 49 cases of enteric fever notifications and 11 "suspicious" cases up to Jan. 4th, and then 9 more notifications, or 69 attacks, with 10 deaths, in one small portion of this little town. It still

Digitized by Google

remains to be learnt what permanent remedy the district council propose to make.

Diphtheria in Huntingfield and Halesworth, by Dr. F. ST. GEORGE MIVART.—These two villages are in the Blything rural sanitary district, where for some time past throat disease of one or another sort has occasioned anxiety; indeed, in the light of the inquiry made it is clear that fatal attacks of croup, croupous laryngitis, and membranous croup were in reality diphtheria. Huntingfield is a parish of only 378 persons; Halesworth, on the contrary, is an ancient market town and contains a population of 2316. In Halesworth diphtheria and allied throat ailments have been occurring ever since 1895, the greatest incidence of the disease being in the periods October–November, 1895; March, 1896; July, 1896; and September, 1896. The disease was essentially limited to the girls' and infants' school, and it would appear that each reassemblage of school children coincided with an increase in the number of attacks amongst those attending school. Dr. F. St. George Mivart enters with much detail into the various sanitary and other circumstances affecting each of the places on which he reports, and also into the local sanitary administration and the measures taken to control and prevent the diffusion of the disease. But, painstaking as the work on his part has been, the story is one, like so many others, in which the identification of the actual condition favourable to the spread of diphtheria is rendered impossible by the many opportunities of conveying the infection from person to person. It is, however, clear from the report that much needs to be done by the Blything rural authority to secure for their population wholesome water at a reasonable distance from their homes, to effect improvement in the local drainage arrangements, to remedy the nuisances arising from defective means of excrement and refuse disposal and other sources, and to deal with faulty conditions in the housing of the poorer classes. In like manner it is to be hoped that the prevalence of an infective disease for so long a period will prove to the authority the need for some means of isolating first attacks, so that these shall not lead to further spread. Dr. Mivart, who was some time since appointed a temporary medical inspector, has shown, in an inquiry that did not easily lend itself to any etiological discovery, that he has distinct capabilities for studying every condition and circumstance likely to elucidate the origin and course of preventable disease.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Brighton Urban District.—The Registrar-General's estimate of the population of Brighton at the middle of 1896 was 120,499, but Dr. Newsholme gives reasons for concluding that the population is somewhat under-estimated, although he takes the Registrar-General's estimate as a basis for the death-rates, &c. The birth-rate for Brighton for 1896 was 25·1 per 1000, being the lowest rate, with the exception of Halifax, of all the thirty-three great towns. Brighton's death-rate was for 1896, the lowest yet recorded for that place, being but 16·1 per 1000, as compared with 18 8 in 1895 and 16·4 in 1894. Dr. Newsholme has worked out the death-rates of the several wards of his district, and in discussing the high rates of certain of the wards he draws attention to the proportion of houses to public-houses, the proportion varying from one public-house to eighteen houses (108 inhabitants) in Pavilion ward, to one public-house to 211 houses (1380 inhabitants) in Preston ward. Dr. Newsholme points out that mortality is indirectly promoted by neglect and partial starvation caused by the waste of money on the part of the bread-winners in the public-houses, while conversely the insufficient accommodation procurable at small rents tends to drive the worker to the public-house for comfort, and so the "evil results of alcoholism and overcrowding act and react in a vicious circle." In treating of the subject of infantile diarrhœa Dr. Newsholme observes that it would be a great gain from a preventive standpoint if sterilised whole milk could be purchased in small sealed bottles during the summer months, and it would seem to us that there can be no doubt that when the risks which milk undergoes in its transit from the cow to the consumer are more fully appreciated by the public, the sale of sterilised milk in the manner suggested will become more common. In the report before us the subject of the prevention of syphilis is touched upon, and Dr. Newsholme reminds his readers that the death records under this head are obviously much understated. He regards syphilis as probably, next to alcoholism, the most fertile cause of ill-health and death. The effects of this disease can only be diminished, Dr. Newsholme considers, "by the enforcement of all preventive measures against known immorality, and of the treatment—and where practicable the segregation—of all men and women who have become infected."

Brighouse Urban District.—Dr. Meredith Young expresses doubt as to whether school closure, for preventing the spread of measles, is a wise measure, and his doubts are founded partly on the contention that children, if relieved from school attendance, spend a large portion of their time outside their houses in all conditions of weather—an exposure which he considers must lower their vitality, and thus their power of resisting infection. He is therefore relying upon the exclusion of infected children and of children from invaded houses. Dr. Young is evidently much impressed with the evils of black smoke in Brighouse, which he regards as a standing disgrace and a danger to public health. He calls attention to the manner in which smoke condenses atmospheric vapour and thus tends to produce a damp and cold climate, while at the same time by preventing the passage of sunlight it deprives the population of the disinfecting property of sunlight and of the stimulating effect which such light produces upon the spirits of the people. The injurious effect of the products of combustion upon architecture and vegetation is also referred to, and it is pointed out that the time limits for "dense" or "moderate" smoke in Brighouse (ten minutes per hour) are much more favourable to the manufacturers than are those in any of the busiest and largest manufacturing towns in the north of England. In reference to the argument that the prevention of black smoke would not prevent the emission of sulphur vapours, &c., Dr. Young insists that these latter are capable of rapid diffusion and are quickly diluted with large volumes of air.

Stoke-upon-Trent Urban District.—The principal trade of the district is that of pottery, and Dr. Samuel Johnson reports that the potters work under much better conditions than heretofore. The workers, however, will not take proper advantage of the respirators which they are advised to use, and the potter, like the Sheffield grinder, regards these devices as eminently irksome. The provisions for preventing lead poisoning are, Dr. Johnson tells us, much improved, as there are now separate mess-rooms for the workers, who are encouraged to wash before taking their meals, and to wear overalls which are left at the works.

Halifax Rural District.—An instance is recorded in Dr. Meredith Young's report for this district of a case of lead poisoning which was apparently due to the consumption of well water which had been in contact with the leaden barrel of the pump. The well water was analysed and found to contain four-fifths of a grain of lead per gallon and to be also organically polluted. It is a somewhat remarkable fact that no symptoms of lead poisoning were observed among several other persons who were habitual consumers of the water in question.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 5709 births and 3310 deaths were registered during the week ending June 26th. The annual rate of mortality in these towns, which had been 15·6 and 15·8 per 1000 in the two preceding weeks, declined again last week to 15·7. In London the rate was 14·6 per 1000, while it averaged 16·5 in the thirty-two provincial towns. The lowest death-rates in these towns were 9·9 in Brighton, 11·1 in Blackburn, 11·8 in Huddersfield and in Leicester, and 12·1 in Bristol; the highest rates were 19·8 in Sunderland, 20·4 in Preston, 20·9 in Liverpool, and 22·3 in Bolton and in Salford. The 3310 deaths in these towns included 404 which were referred to the principal zymotic diseases, against 379 and 354 in the two preceding weeks; of these, 167 resulted from measles, 77 from whooping-cough, 68 from diarrhœa, 46 from diphtheria, 29 from scarlet fever, and 17 from "fever" (principally enteric). No deaths from any of these diseases were recorded last week either in Croydon, Swansea, or Norwich; while they caused the highest death-rates in Bolton, Manchester, Salford, and Preston. The greatest mortality from measles occurred in Burnley, Liverpool, Bolton, Cardiff, Manchester, Preston, and Salford; from whooping-cough in Derby, Sunderland, and Manchester; and from diarrhœa in Preston. The mortality from scarlet fever and from "fever" showed no

Digitized by Google

marked excess in any of the large towns. The 46 deaths from diphtheria included 24 in London, 6 in Birmingham, and 3 in West Ham. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and there were no cases of this disease under treatment in any of the Metropolitan Asylum Hospitals on Saturday last, June 26th. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2789, against numbers increasing from 2380 to 2670 on the eight preceding Saturdays; 267 new cases were admitted during the week, against 274, 255, and 274 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 191 and 141 in the two preceding weeks, were 142 last week, and were 71 below the corrected average. The causes of 59 or 1·8 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Nottingham, Hull, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Leicester, Preston, Halifax, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 19·4 per 1000 in the two preceding weeks, was again 19·4 during the week ending June 26th, and exceeded by 3·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·7 in Paisley and 15·8 in Aberdeen, to 27·1 in Greenock and 35·8 in Paisley. The 577 deaths in these towns included 21 which were referred to measles, 20 to diarrhœa, 16 to whooping-cough, 6 to "fever," 4 to scarlet fever, and 2 to diphtheria. In all, 69 deaths resulted from these principal zymotic diseases, against 94 and 87 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2·3 per 1000, which was 0·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had declined from 30 to 24 in the three preceding weeks, further fell to 21 last week, and included 10 in Edinburgh and 9 in Leith. The deaths from whooping-cough, which had been 37 and 29 in the two preceding weeks, further declined to 16 last week, of which 10 occurred in Glasgow. The deaths referred to different forms of "fever," which had been 8 and 5 in the two preceding weeks, were 6 last week, of which 5 were recorded in Glasgow. The 4 fatal cases of scarlet fever were within 1 of the number in the preceding week, and included 2 in Aberdeen. The deaths from diseases of the respiratory organs in these towns, which had been 108 and 109 in the two preceding weeks, declined to 104 last week, but exceeded by 17 the number in the corresponding period of last year. The causes of 41, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the four preceding weeks from 28·3 to 19·7 per 1000, rose again to 21·8 during the week ending June 26th. During the past twelve weeks of the current quarter the death-rate in the city has averaged 27·9 per 1000, the rate during the same period being 15·7 in London and 25·5 in Edinburgh. The 146 deaths registered in Dublin during the week under notice showed an increase of 14 upon the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 14 in each of the two preceding weeks; of these, 5 resulted from diphtheria, 2 from measles, 2 from diarrhœa, 1 from scarlet fever, and 1 from whooping-cough. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·6 in London and 2·7 in Edinburgh. The fatal cases of diphtheria, which had been 1 and 3 in the two preceding weeks, further rose to 5 last week. The deaths referred to measles, which had declined from 5 to 1 in the four preceding weeks, rose again to 2 last week. The mortality from scarlet fever and from whooping-cough was below that recorded in any recent week. The 146 deaths in Dublin last week included 28 of infants under one year of age, and 32 of persons aged upwards of sixty years; the deaths of infants showed a slight decline, while those of elderly persons exceeded the number in the preceding week. Eight inquest cases and 8 deaths from violence were registered; and 52, or more than a third, of the deaths occurred in public institutions. The causes of 8, or more than 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN H. I. POCOCK has proceeded to Devonport, and will subsequently proceed to Aldershot for field training. Brigade-Surgeon-Lieutenant-Colonel R. C. Eaton has assumed charge of the Station Hospital, Newcastle-on-Tyne. Surgeon-Captain Corkery has been transferred from Bermuda to the Cork District in exchange with Surgeon-Major Donaldson. Surgeon-Major Johnston has returned from Okehampton to Devonport, and assumed Command of the 1st Field Hospital about to be mobilised.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain Jackson, A.M.S., are replaced at the disposal of the Government of India, in the Home Department. Surgeon-Lieutenant-Colonel A. E. R. Stephens, Bengal Establishment, retires from the service subject to Her Majesty's approval, as does also Surgeon-Lieutenant-Colonel S. B. Haliday.

ARMY MEDICAL RESERVE OF OFFICERS.

The under-mentioned Surgeon-Captains to be Surgeon-Majors:—G. Harrison and W. H. Packer, M.D.

VOLUNTEER CORPS.

Artillery: 1st Essex (Eastern Division, Royal Artillery): Surgeon-Captain A. Morris resigns his commission. 1st Glamorganshire: David Arthur Davies, M.B., to be Surgeon-Lieutenant. *Rifle:* 2nd (the Weald of Kent) Volunteer Battalion the Buffs (East Kent) Regiment: Surgeon-Lieutenant H. W. Joyce resigns his commission. 5th (the Hay Tor) Volunteer Battalion the Devonshire Regiment: Surgeon-Major W. G. Scott, M.B., resigns his commission. 1st (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: Surgeon-Major D. B. Balding to be Surgeon-Lieutenant-Colonel. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant A. J. Anderson, M.B., resigns his commission. 2nd Volunteer Battalion the Durham Light Infantry: Brigade-Surgeon-Lieutenant-Colonel J. Mitchell resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement, vacating at the same time his appointment in the Tyne and Tees Volunteer Infantry Brigade. 1st Dumbartonshire: Surgeon-Lieutenant W. Little, M.D., resigns his commission.

A HOSPITAL WITH A HISTORY.

The military hospital at La Rochelle lately visited by President Faure has a remarkable history, which not only contains an interesting and instructive moral, but is likewise perfectly authentic. Towards the commencement of the thirteenth century M. d'Aufredi, a worthy owner and equipper of privateers, was one of the most important inhabitants of the important haven of La Rochelle. Being very rich and hospitable his list of friends was naturally an extremely lengthy one, and thoroughly satisfied with his lot he thought he was the happiest of men. One morning, however, the alarming rumour spread with characteristic speed that the whole of his fleet had been engulfed during a tempest in the Indian Ocean, and the unfortunate merchant awoke to find himself utterly ruined. The friends to a man turned their backs on him, and the ex-possessor of millions was compelled to become a porter in order to earn a miserable livelihood, while his wife, the incomparable Pernelle, sold fish in the public streets. In this way two years passed slowly by. Then, one fine afternoon, lo! two ships appeared on the horizon making their way towards the harbour, and presently they arrived close enough to be recognised. The returning vessels formed the van of d'Aufredi's squadron, which ere long hove in sight laden to the water's edge with the choicest treasures of the East. Needless to say, the friends were now loud in their offers of

Digitized by Google

service and assurances of undying affection, but, like Timon, d'Aufredi would have none of them. He and his admirable wife resolved to devote themseves and their recovered wealth to the cause of the poor and suffering, with whose good qualities they were now acquainted. During their period of trial they had received much kindness from their humble neighbours, and in order to benefit the class whose members did good without any expectation of reward they decided on founding and endowing the hospital that still bears their name. For close on twenty years the devoted pair continued to minister personally to the needs of the patients, and when at length death claimed his dues the whole of their fortune became the property of the institution. An inscription, setting forth the facts as above related, is to be seen in the vestibule of the existing building.

THE LATE ADMIRAL SIR WILLIAM MENDS, G.C.B.

The death at Alverstoke, Hants, on June 26th, of this old and very distinguished officer should not pass unnoticed in our columns, for the late admiral took part in many transactions affecting the medical services, and it is well known that he was greatly interested in the welfare of medical officers generally. He was one of the best type of naval officers of the past generation—single-minded, fearless, independent, and enterprising. Nothing could have exceeded his thoughtful care and consideration in meeting the views and wishes of the Army Medical Service in fitting out the *Victor Emmanuel* as a hospital ship for the first Ashanti expedition under Sir Garnet Wolseley. Admiral Sir William Mends, in order to meet the views of the medical service, executed a number of proposals which had never before been adopted under such circumstances, with the result that the late Professor Parkes said it was altogether the best and most perfectly fitted out hospital ship that had ever left the shores of this or any other country. Admiral Mends also rendered the medical officers of the army very opportune and independent support as a member of the commission of inquiry appointed at the end of the Egyptian war of 1882. On the conspicuous part he played as a naval officer and seaman on several occasions during his active service there is no need to dwell, for this is well known—in fact, a matter of naval history.

HEPATITIS AND ALCOHOL.

In a recent article on the health of the Spanish army Dr. Vantalon draws attention to the remarkable immunity from hepatic affections enjoyed by the European troops quartered in the Philippine Islands. Dysentery, the constant associate, or forerunner, of inflammation of the liver is very prevalent, causing heavy mortality in addition to serious loss by invaliding; but hepatitis is not even mentioned in the returns. Evidently the omission cannot be an oversight; it must be due to the non-occurrence of an affection which elsewhere within the intertropical region, and especially at Tonkin, is so widespread and fatal. The author is inclined to attribute this exemption of the Spanish soldiery from one of the most deadly of Oriental diseases to their admirable and universal sobriety. They one and all eschew the horrible compounds of which such alarming quantities are habitually consumed in French colonies under the fallacious designation of *apéritifs*. The name of these vile poisons is legion; and nothing conduces more to gastro-intestinal trouble than the pernicious custom of "nipping"—that is, of drinking small quantities of undiluted, or very slightly diluted, spirit—at all hours and under any pretext.

THE SURVIVORS OF THE BALACLAVA CHARGE.

Mr. T. H. Roberts, of 158, Fleet-street, had the happy idea of entertaining, on the occasion of the Diamond Jubilee, the survivors, some seventy in number, of the Light Brigade who fought at Balaclava. Twenty of these he found in very needy circumstances, and two of them, we are sorry to say, came out of the workhouse. Mr. Roberts is anxious to raise a fund so as to provide at least food and shelter for these men for the remainder of their lives. They are all about seventy years of age—a time of life when a man may reasonably expect a little rest. If any of our readers feel inclined and are able to send something for this good object Mr. Roberts will gladly receive it, and he has generously undertaken to defray all expenses connected with the collection and administration of the fund.

IMPROVEMENT OF THE FIELD RATION FOR THE NATIVE ARMY OF INDIA.

Among the questions, says the *Pioneer Mail* of the 9th ultimo, engaging the attention of the Indian military authorities is that of improving the rations of sepoys and followers on field service. The experience gained in frontier expeditions shows that a change is necessary, as the ration invariably has to be supplemented with extras. The serious outbreak of scurvy in the Indian brigade at Suakim, where the officers as well as the men suffered, was also too significant to be overlooked.

SURGEON-GENERAL H. T. READE, C.B., V.C. (RETIRED).

We much regret to record the death of this distinguished officer, who was a brave, conscientious, single-minded, and most amiable man. A short obituary notice will be found in another column.

DEATHS IN THE SERVICES.

Surgeon-Captain Christopher Clemons Cassidy, I.M.S., from the effects of the wounds received in the Tochi attack. He entered the service in 1891.

NEW HOSPITAL AT BARRACKPORE.

We learn from the Indian papers that a new hospital for British troops is about to be built at Barrackpore at a cost of Rs. 95,000.

Correspondence.

"Audi alteram partem."

"ON THE MECHANISM BY WHICH THE FIRST SOUND OF THE HEART IS PRODUCED."

To the Editors of THE LANCET.

SIRS,—I read with great interest the able article on the above subject in THE LANCET of June 19th by Sir Richard Quain, and when I had finished reading I said, These views are those of the late Dr. Arthur Leared, with whose writings evidently Sir Richard Quain is not acquainted. I then hunted out Dr. Leared's graduation thesis,[1] which I had not perused for nearly twenty years, and I there found my impressions amply corroborated, but that I may do no injustice either to the dead or the living I shall quote very freely from Dr. Leared's work, and then your readers can readily compare his views with those of Sir Richard Quain. "All sounds formed in connexion with the circulation are produced by and in the blood itself, and their mechanism is virtually the same. If this statement be true it would be found in practice that a sound of one species would be liable to be changed into a sound of another species. And this is the case, for the normal first sound of the heart is under certain pathological conditions converted into a murmur; and, on the other hand, a murmur thus produced may again give place to the natural sound. In short, all the sounds may be regarded as modifications of a typical sound, because under varying circumstances they are convertible into each other." He then gives a series of experiments in support of these views, from which he draws the following conclusions: "Two important principles were established by these experiments. First, that sounds may be formed by the motion of fluids only. Second, that the quality of a sound thus formed is materially influenced by the nature of the fluid. The sounds formed by the circulation of the blood are produced on principles similar to those detailed in these experiments. I shall, therefore, for convenience, and as conveying their true nature, designate them as blood sounds. Blood sounds are divisible into two classes—sounds which give the impression of a shock; sounds which give the impression of a current. Shock sounds (*bruit de choc* of French authors) comprise the normal sounds of the heart, and certain abnormal sounds formed in aneurysmal sacs. Current sounds are formed in the heart, in aneurysmal sacs, and in the larger arteries and veins. These sounds are all abnormal; they are extremely diversified; some closely resemble shock sounds, others are aptly compared to the blowing of bellows, to rasping, sawing, cooing, &c."

It is thus seen that Dr. Leared's theory also accounted for the production of murmurs, and the similarity of his

[1] On the Sounds Caused by the Circulation of the Blood. London: John Churchill, 1861.

Digitized by Google

views with those of Sir Richard Quain as to the causation of the first sound will now become apparent. "We are now in a position to comprehend the formation of the sounds of the heart. If the condition of the blood through the heart and arteries were equable no sounds whatever would be produced in a state of health. But the blood is, by the action of the heart, thrown into impetuous and interrupted motions, and these give rise to normal sounds, known as the first and second sounds of the heart. Both are formed in the outlets of the two great vessels,[2] and the mechanism of both is essentially the same. The *first sound* coincides with ventricular systole and is caused as follows: Blood having been forcibly driven from the ventricles into the aorta and pulmonary artery comes into forcible contact with blood in these vessels which, supported by the semilunar valves, had attained a state of momentary repose. The impact between the fluid in motion and that in a state of rest gives rise to the sound. The well known thumping sound heard during the action of the common forcing pump is chiefly due to an analogous cause—that is, to the impact between the water thrown into violent motion and stationary water in the discharge pipe. But the analogy between the conditions causing the heart sound and those causing sound in the experiment with glycerine is more complete than might be at first supposed. The column of glycerine forcibly driven through the glycerine at rest does not, owing to its viscidity, diffuse itself so as to cause friction between its molecules and those of the surrounding fluid sufficient to produce murmur, and an imperfect shock sound results. But enclosure in a tube of both the moving and stationary blood, and their separation by valves, greatly favours the development of sound on the same principles. Four conditions are necessary for the production of the perfect first sound:—(1) Sufficient viscidity of the blood; (2) sufficient force in the circulation; (3) sufficient pressure upon the blood; (4) the absence of obstruction at the outlets of the heart.

"When all these conditions are fulfilled the result is a true shock sound. If, however, the first condition, viscidity, is wanting, we find in place of it the blowing sound of anæmia, as already mentioned. The force of the adult left ventricle has been variously stated, but the estimate of Valentin, that it is sufficient to overcome a resistance of 4 lb. seems probable. It is, at all events, certain that when the force of the heart is much diminished, as occurs in certain fevers and in syncope, the first sound becomes impaired or is altogether lost. The fact that pressure upon the blood prevents murmur by preventing friction need not be here repeated. A common cause of diminished pressure is incompetency of the intracardiac valves, since regurgitation reduces the volume of blood sent into the outlet vessels. The fourth condition, absence of abrupt interference with the current, is resolvable into the third. For any obstruction at the mouth of the aorta or pulmonary artery, whether it be contraction of its calibre or the projection of an atheromatous deposit, must cause diminished pressure in the vessel beyond the obstruction. The principles upon which *bruit de soufflet* is then formed have been already detailed.

"It is highly probable that a deviation in any of these conditions, although too slight to destroy the character of the sound, causes a corresponding modification of it. The water and glycerine used in separate experiments respectively represented exaggerated conditions of thinness and viscidity of the blood, and I have obtained intermediate results by employing fluids of medium viscidity. But the delicate relation between pressure and viscidity that exists in the living body was wanting in the experiments. A close study of this relation will alone throw light on the modifications of all the sounds produced by the circulation. Everyone accustomed to study the heart's sounds must have observed wide variations in these sounds, even regarded as within the limits of health. For instance, in the robust subject we frequently hear sounds of a dull and muffled character compared with the loud and resonant sounds in the delicate. These facts cannot be explained on any prevailing theory of the heart's sounds, but are entirely in accordance with my views—that unusual pressure and viscidity, by which are implied an abundance of blood rich in fibrin as would occur in a vigorous subject, cause the sounds to be relatively low. Probably impairment or loss of the first sound in certain fevers in which the fibrin of the blood is known to be in excess is partly due to consequent increased viscidity. The first sound is always affected in fever before the second, and this circumstance, as well as the fact that the second is much less subject to alterations than the first, will be afterwards seen also to depend on the mechanism of the sounds at present advocated."

Dr. Leared's views were not widely accepted, nor did they perhaps receive that attention which they merited. He, however, held firmly to them, and in a letter which I had from him a short time before his death he said: "We would agree to differ." Sir George Johnson tentatively adopted Dr. Leared's shock theory, apparently because it seemed to explain his theory of the causation of a double first sound, but although he afterwards dropped Dr. Leared's views, and allowed the whole foundation on which his theory was built to be cleared away, yet he adhered with his usual pertinacity to his hypothesis that the auricle produced the first element of a double first sound. Blood is an incompressible fluid, and the sudden impact of a column in motion against one at rest, or the sudden arrest of a column in motion, must set up vibrations, but that the sounds of the heart are thus *directly* caused is quite another matter. A soft tallow candle in a rifle can be driven through an inch board, and no doubt a similar force applied to a column of liquid—a less compressible body—would have a similar effect. A small jet of water at the bottom of a deep reservoir issues with great force, and will produce audible vibrations against any obstructions to its exit, but that the violence necessary to produce an audible shock between the columns of blood in the heart and great vessels is ever present in the heart I very much doubt. A few nights ago I saw with Dr. Murdoch a patient suffering from aortic regurgitation; the violence of this heart and its recoil were sufficient, not merely to shake the body of the patient, but also the bed on which he lay. This rifle heart did not produce any particularly loud first sound.

If I were to accept the views of Dr. Leared and Sir Richard Quain I would be quite prepared to go a step further and express an opinion that the Great Designer had not provided us with a very perfect pump, and I would mildly suggest that He should have followed the lines of water companies, and put something like a screw tap, rather than a stopcock, on the main vessels. The shock produced by a column of blood sufficient to cause the first sound of the heart would verberate and reverberate throughout the whole arterial tree, and I should not like to hazard an opinion as to the strength of tubing which would be required to endure such repeated shocks for three score years and ten. It is true Dr. Leared advances a similar view against the valvular theory.

"Dr. Markham asks, 'Can membranes and chords be suddenly and forcibly stretched and remain toneless?' I venture to ask, Is it possible that we constantly suffer so much internal violence and survive?"

I quite accept this idea of violence to the valves, and think that in disease we are often called upon to modify it. I believe it is mechanical violence which determines the much greater frequency of diseased valves in the left than in the right side of the heart in cases of acute rheumatism. The violent impact of the mitral cusps sets up a proliferation of the sub-endothelial layer, which bursts through the endothelium and gives rise to a row of fine vegetations along the auricular surface of the edges of the valve, just where the cusps are brought into violent apposition. In the case of the aortic valve the vegetations first occur on the ventricular surface just where the semilunar segments are brought into forcible contact by high tension in the aorta. In order to prevent heart lesions in acute rheumatism I always see that the arterial tension is kept low by the use of salines, &c. Again, the long-continued strain on the mitral valve in cases of granular kidney leads to thickening of the cusps and often to narrowing of the orifice. If the right side of the heart was subjected to the same strain it is probable that its valves would not so frequently escape. I have long been in the habit of diagnosing the condition of the valves from the character of the sounds, and my treatment has been much influenced thereby. I have at present no intention of bringing forward any constructive theory as to the cause of

[2] "On this point the assertion of so competent an authority as Cruveilhier is worth quoting. In his examination of the remarkable case of an infant born with heart exposed he found that the maximum intensity of both sounds was at the same place—the base; and he observes, 'Hence it is at the base of the organ we are to look for the cause of these sounds.'"—Cruveilhier, Gazette Médicale de Paris, 1841.

Digitized by Google

the first sound of the heart. My object now is purely destructive; and if I have contributed in any way towards the demolition of the theory set up by Sir Richard Quain I shall feel satisfied. No doubt this theory has already received the *imprimatur* of Dr. Pettigrew, but that neither establishes its accuracy nor its originality.

I am, Sirs, yours faithfully,

Liverpool, June 20th, 1897. JAMES BARR.

THE TEETH OF TO-DAY.

To the Editors of THE LANCET.

SIRS,—Caries of the teeth is by no means a new disease, as the examination of Egyptian mummies 2000 years old shows; but taking modern times and civilised communities there can be no doubt as to its increasing prevalence in the present generation. This statement is based upon the results of a series of examinations of the teeth and jaws in skulls of different periods, both British and foreign, by clinical observation and the law of supply and demand, the number of dentists increasing in a ratio out of all proportion to the increase in the population. Some think, and perhaps with a certain amount of truth, that this increase in disease is more apparent than real, as so much more importance is attached to the teeth both from a health and æsthetic point of view; but that former generations appreciated good teeth may be gathered from the works of Smollett, Fielding, Mrs. Radcliffe, and others, in which the heroine is invariably described as having "pearly teeth." Our premisses being granted, it behoves us to endeavour to discover the causes of this degeneration with a view to their removal where possible. "Degeneration may be defined," says Ray Lankester, "as a gradual change of the structure in which the organism becomes adapted to less varied and less complex conditions of life; whilst elaboration is a gradual change of structure in which the organism becomes adapted to more and more varied and complex conditions of existence. In elaboration there is a new *expression* of form corresponding to new perfection of work in the animal machine. In degeneration there is *suppression* of form corresponding to the cessation of work." Degeneration is doubtlessly taking place in the teeth and jaws of man.

In structure and character the teeth are becoming more and more faulty, having, perhaps, pits in the enamel and jagged edges—honeycombed teeth—fissures, grooves, and other imperfections not traceable to disease. Microscopically, the dentine often presents cavities in its substance known as "interglobular spaces" and due to imperfect calcification, all of which lesions render them liable to caries. It was until quite recently believed that teeth which easily fall a prey to caries were deficient in lime salts, but the elaborate experiments of Black in America and Charles Tomes in this country have disproved this view. Numerically the teeth are becoming less, the wisdom tooth often failing to make its appearance, and perhaps the absence of the superior lateral incisor is more frequently observed. The shape of the jaw is changing from the square to the V-shaped, the so-called "educated jaw," and this is generally associated with irregularity, which is a potent predisposing cause of caries. The main factor of this degeneration and the prevalence of caries is to be found in the modern mode of living and civilisation generally. Let us take the life-history of a tooth temporary and permanent. First, in its embryonic stage, the mother while pregnant, if in the lower class, must necessarily go about her work as usual, and added to that there are those frequent strikes entailing so much privation and anxiety. What sort of children does one expect these women to bear? Weak, sickly, puny, probably rickety, and certainly with mal-developing teeth. And if in the higher ranks of life the future mother still pursues her round of gaiety and fulfils her social obligations. Now, would Lord Rosebery or any breeder of horses allow his mares when in foal to work? Moreover, it is becoming less and less common for mothers in the upper classes to suckle their children, and all this must have a deleterious effect on the developing teeth.

Later, when the second set are erupting or not yet fully calcified, our children lead a very different life to those of our ancestors—far more excitement, late hours, cultivation of the intellect at the expense of the physique, and cramming at school all tend to injure the developing teeth both by interfering with nutritional changes and locally by bringing about an unhealthy condition of the mouth. By the way, I think that sweets as a cause of decay have been much maligned. Sugar is the natural food of children; if not, why should the taste be so universal and why sugar in mother's milk? I believe they do harm only when causing dyspepsia. And now I come to adults, in whose teeth it is generally maintained that vital action in the pulps has no influence upon the courses of caries, although I am somewhat of a sceptic on that point. Here, again, the high pressure of modern civilised life is an important factor, both as to the occurrence of caries in the individual and the transmission of degenerate teeth to the offspring. The constant whirl of excitement, whether in the pursuit of pleasure or gain, accompanied too often by the neglect of physical exercise, brings about a state of nervous exhaustion and frequent attacks of dyspepsia. And during all these periods how little work the teeth and jaws have been called upon to do with our modern cooking! This disuse of the masticatory apparatus acting through successive generations has produced degeneration and consequent proneness to disease. I have still one more predisposing cause to mention which ought not to be overlooked from a scientific point of view, though of little value from the practical side, and that is "natural selection." Men marry women with the ovoid face with narrow jaw, and not those with square massive jaws, and, further, those teeth of an azure colour and translucent appearance, which are so frail, are generally admired, not the strong yellow teeth.

I am, Sirs, yours faithfully,

W. SCOTT THOMSON, M.R.C.S., L.D.S. Eng.

Bentinck-street, W., June 1897.

CANCER AND "MORBUS MISERIÆ."

To the Editors of THE LANCET.

SIRS,—In most modern text-books on gynæcology reference is made to the alleged greater prevalence of cancer among the poor and ill-nourished than among those more fortunately circumstanced. This doctrine has lately received its apotheosis at the hands of Dr. Sinclair, who says[1]: "My experience is that uterine cancer occurs only among the working classes; the apparent exceptions are so few that they are hardly worth discussing." Elsewhere he adds: "Cancer of the uterus is most frequently met with in the lower ranks of the people of all countries. So marked is the difference of incidence that it might be reasonably affirmed that if we could place all the lower orders who suffer from privation and depressing environment for a generation or two in the position of the more favoured, we should stamp out cancer." Against the acceptance of this misleading doctrine I would urge the following considerations:—1. During the last half-century the wealth of the country has more than doubled; its pauperism has diminished more than one-half; crime has steadily declined; sanitary conditions have greatly improved; the mortality from zymotic, tuberculous, and many other diseases has markedly diminished; wages have gone up, while the prices of most commodities have fallen to an extraordinary extent; the consumption of meat per head has more than doubled, having now reached the amazing total of 126 lb. per year; the bulk of the people are better paid, better housed, and better fed than ever they have been before—in short, just such conditions have prevailed as Dr. Sinclair alleges are necessary to stamp out cancer; but instead of having decreased during this period the *cancer mortality has more than quadrupled*, the uterus participating in due proportion. 2 The Registrar-General's reports show that the cancer mortality is *lowest* where the struggle for existence is hardest, where the conditions of life are most squalid, the density of population greatest, the tubercle mortality highest, the general mortality highest, and where sanitation is least perfect,—in short, among the industrial classes in our great towns; whereas among the wealthy and well-to-do, and among the agricultural community, there the cancer mortality is *highest*. The experience of those engaged in prisons, workhouses, and lunatic asylums points in the same direction, for cancer is comparatively rare among the inmates of such institutions, as it is also among the intemperate. Of like import is the great frequency of the disease in civilised communities, whereas among savages it is almost unknown. 3. The *ensemble* of facts relative to the life-history of cancer

[1] Allbut's System of Gynæcology, 1897, p. 657.

Digitized by Google

patients shows that they have almost invariably led regular, sober, and industrious lives. Persons of drunken and dissolute habits are comparatively seldom affected. Of 160 uterine cancer patients under my observation not a single one, so far as I could ascertain, had ever been addicted to prostitution; and, what is still more remarkable, only one presented undoubted signs of having had syphilis. The marked fecundity of uterine cancer patients, the rarity of sterility and abortion among them, all point in the same direction, for such conditions are of frequent occurrence in prostitutes and in the syphilitic. Such considerations as the foregoing seem to me to negative the doctrine of cancer being *morbus miseriæ*. They point to the greater prevalence of the disease among the well-to-do and easy-going, who habitually eat more than is good for them.

I am, Sirs, yours faithfully,

June 24th, 1897. W. ROGER WILLIAMS, F.R.C.S. Eng.

"UNQUALIFIED PRACTICE IN CORNWALL."

To the Editors of THE LANCET.

SIRS,—Referring to your leading article in THE LANCET of June 26th, will you kindly allow me to indicate two points which the President of the General Medical Council and his colleagues may press upon the President of the Local Government Board? The first is that the Select Committee of the House of Commons appointed to inquire into the subject of death certification reported some years ago, their first recommendation being that no death should be registered without a certificate from a duly registered medical practitioner or from a coroner after inquest. It is well known that the registrar has power to accept the best information he can get when no medical certificate is forthcoming and there are no grounds for referring the case to the coroner. It would surely only be reasonable to urge that the Registrar-General should give effect to the recommendation of the committee, and instruct his officer to refer every death not certified by a duly registered medical practitioner to the coroner. This would effectually close what is at present a most dangerous loophole for irregular practice. The second point is that which you have indicated near the end of the article: "It is high time that the whole system of unqualified practice in all its forms was more systematically studied by the General Medical Council." Liverpool has, like most seaports, swarmed with advertising quacks for the last forty-five years to my knowledge. These men practise and advertise with an effrontery which is evidently their strong point, and which would appear to recommend them to the public. One of these men was convicted some years ago of obtaining money by fraud, and was sentenced by Mr. Justice Day (who lamented that it was the highest sentence he could give him) to five years' penal servitude. His qualification consisted of a conviction for theft and of his having been for years a bill-sticker for another local quack, who fled to escape justice some years ago. Shortly after his conviction the name of a duly registered surgeon who had been associated with him in his infamous work was erased from the Medical Register; but so far from the establishment being broken up, as might have been expected, it flourishes more than ever, being kept up by the convict's wife, assisted by the ex-registered surgeon, whose name appears boldly on a brass plate as Mr. ——, surgeon, and by a Dr. ——, whose name also appears on a brass plate with the words physician and surgeon. The first name also appears as surgeon in two places in the local directory. It was stated at the trial that the convicts' receipts for years past had amounted to several thousands annually, and at a recent inquest on the body of a woman who had been under the care of Dr. —— and Mr. —— the weekly cash receipts were given and were very large. Is there no remedy for such a state of things?

I am, Sirs, yours faithfully,

Liverpool, June 28th, 1897. FRED. W. LOWNDES.

CYCLING FOR WOMEN: ITS EFFECTS ON PARTURITION.

To the Editors of THE LANCET.

SIRS,—Two cases that I have recently attended show that frequent bicycle exercise and continued pressure of a hard saddle may act as a cause of delay in the second stage of labour. Both were primiparæ, of good physique, and accustomed to daily riding, in some cases long distances. The presentation was natural in each case and the labour easy until the head rested on the perineum, which was unusually tough and unyielding. The bowels and bladder had previously been emptied, and the child's head was of moderate size. After applying the usual remedies and waiting a considerable time delivery was quickly effected with short forceps without tearing the perineum in the slightest. It seems quite probable that long rides and the use of hard saddles caused the difficulty in these two cases, and it is as well perhaps that attention should be directed to the possible inconvenience and trouble which may result from an immoderate use of the wheel, and that care should be exercised in the choice and position of the saddle.

I am, Sirs, yours faithfully,

June 28th, 1897. J. W. MCVITIE, M.R.C.S. Eng.

THE COUNTRY HOLIDAY FUND: AN APPEAL TO COUNTRY PRACTITIONERS.

To the Editors of THE LANCET.

SIRS,—Many of your readers are country readers. They must know of cottages where grown-up children have left empty places or where for other reasons there are rooms ready for guests. Would they tell of such rooms to the secretary of the Country Holiday Fund, 10, Buckingham-street, Strand? There are now some thousands of town children ready for holidays. They will enjoy them in the country, but they will enjoy them much more if they can, during their country visit, share the life of a country family, experience the different habits of living, and get familiar with the talk and life of those who have to work with growing things. The payment for each child is 5*s.* a week, and every precaution is taken that the child shall be free from all disease. I am, Sirs, yours faithfully,

Toynbee Hall, Commercial-street, E. SAMUEL A. BARNETT.

*** If any of our country readers can give Canon Barnett the information he desires they may benefit some of their own poorer neighbours as well as the little people in whose particular behalf he writes.—ED. L.

"OBSERVATIONS UPON RE-VACCINATION."

To the Editors of THE LANCET.

SIRS,—In the "Observations upon Re-vaccination" which he communicated to THE LANCET of June 12th Dr. Robert Carter advocates that in small-pox epidemics every child in whose case four years have elapsed since primary vaccination should be re-vaccinated. I should not be disposed to question this conclusion of Dr. Carter's if he had urged in its favour that much vaccination performed in this country is of poor quality, and that in consequence it is expedient in times of small-pox prevalence to re-vaccinate all children after four years in order to secure immunity to those who have not received at the time of primary vaccination the highest degree of protection which vaccinia affords against attack by small-pox. Again, had Dr. Carter maintained his thesis on the ground that, as an occurrence wholly exceptional, children have been known to contract small-pox—though necessarily of the mildest type—within four years of efficient vaccination, the argument would have been sound, if not altogether convincing. But the reason which Dr. Carter gives is of a different nature. It is that he has found children susceptible to vaccinia, in greater or less degree, as early as four years after their primary vaccination. It would have been interesting to know whether any difference was observed in the reaction of these children to re-vaccination according as they presented good, bad, or indifferent marks of primary vaccination. But, setting this question aside, has it ever been seriously claimed that the duration of the insusceptibility to vaccinia which a vaccinated person acquires is the same as the duration of that individual's insusceptibility to attack by small-pox? The distinction between the two cases was pointed out by Jenner, and has been illustrated again and again in small-pox epidemics. It would be curious if evidence of the greater duration of the protection against small-pox attack could

Digitized by Google

not have been found, for instance, in the outbreak to which Dr. Carter refers. I am, Sirs, yours faithfully,

London, June 15th, 1897. G. S. BUCHANAN.

A CASE OF SUDDEN DEATH.

To the Editors of THE LANCET.

SIRS,—In Dr. Dixon Mann's interesting article on Unexpected Deaths from Natural Causes he includes gall-stone colic among those diseases which when fatal do not usually end suddenly, but may exceptionally do so. The following case, which came under my notice in October, 1895, is, I think, of some interest in this connexion. I was called from bed at night to attend a patient whom I had not previously seen, a woman, some fifty-five years of age, living alone in lodgings. She was dead before my arrival, and the people of the house feared that she had died from the effects of poison, self-administered. Their story was briefly as follows. She had complained all day of feeling unwell and had remained in bed secretly solacing herself with brandy. Shortly after twelve o'clock, when the household had retired, she rang her bell furiously, and was found rolling upon the bed in great agony. She complained of severe pain in the abdomen and chest and said: "Give me something to make me sick; if you don't give me something to make me sick I shall die." She repeated these words more than once, was violently sick, and died. A bottle half filled with brandy lay on the bed and several empty bottles were concealed in the room. I took away with me some of the vomited matter and tested for the more common irritant poisons. It contained alcohol in abundance, but I could detect nothing else. By the coroner's order I made a post-mortem examination. The gall-bladder was greatly distended by calculi of all sizes to the number of a hundred or more. One of the smaller stones was impacted in the common bile-duct. There was extensive fatty change in the heart muscle. At the inquest a verdict was returned of death from syncope during an attack of biliary colic.

I am, Sirs, yours faithfully,

Leicester, June 29th. T. V. CROSBY, M.B. Lond.

"DEATHS AFTER OVARIOTOMY": A CORRECTION.

To the Editors of THE LANCET.

SIRS,—My attention has just been drawn to a mistake in my wording of a footnote (No. 5) on page 1538 of THE LANCET of June 5th. The note in question should read as follows: "The hot water used for this purpose has in every instance been obtained from the usual domestic boiler-supply, its temperature being regulated when necessary by the addition of *cold water previously sterilised by boiling*."

I am, Sirs, yours faithfully,

June 28th, 1897. W. A. MEREDITH.

"SURGERY: ITS REMARKABLE PROGRESS DURING THE REIGN."

To the Editors of THE LANCET.

SIRS,—I beg to call attention to a slight error in your valuable journal of June 19th under the above heading. You state in your article that "the introduction by *Leiter* of the cystoscope has greatly facilitated the diagnosis and treatment of diseases of the bladder." The *introducer was my late master, Nitze, of Berlin.* Leiter was only the manufacturer of this instrument. Hoping you will find space for this correction, I am, Sirs, yours faithfully,

Budapest, June 25th, 1897. DR. SAMUEL BAUMGARTEN.

THE LUNACY ACT, 1890, AND ITS AMENDMENTS.

To the Editors of THE LANCET.

SIRS,—The principal objects of the Lunacy Act, 1890, were stated in the "Memorandum" to be to furnish safeguards against the improper confinement of persons as lunatics; to remove the difficulty then felt in securing the speedy treatment of mental disease; to amend the law as to single patients; and to put a check upon the establishment of new licensed houses. A second Amending Bill to the above Act being now before the House of Lords the time seems favourable for considering how far the objects aimed at in the original Act have been attained during the seven years it has been in operation. On the one hand, complaints are daily heard from asylum officials of the great difficulty they experience in carrying out the numerous, and, as some think unnecessary, provisions of the Act, and of the vastly increased amount of clerical and other labour which it entails; whilst, on the other hand, it is said that the Act is evaded, that secret, illegal, and irresponsible "treatment" of the insane, and those threatened with insanity, flourishes and increases. A very influential deputation have just waited upon the Lunacy Commissioners and appear to have spoken strongly and frankly upon the latter facts.

Dr. Blandford, a member of the deputation, is reported to have said: "The intervention of the magistrate presented the greatest difficulty; the friends of the patient make every possible objection to going before the magistrate; and medical men are getting more and more afraid of signing certificates." Dr. Savage said: "At the present moment every person, whether he is a decayed gentleman or a decayed person, thinks he is justified in taking a person of unsound mind into his house, and applications are made by hundreds and hundreds of them. He believed that if it were known that there was a possibility of the cases being occasionally visited most of those people would not apply to have persons of this kind in their houses." He believed that "the present circumstances tended to secrecy." Mr. Bagot, chairman of the Commissioners, said: "There was another side to this question; he would ask, which is best—for the patient to be treated in a scientific way in an asylum, or casually in a private house?" He drew attention to the legal aspect of the case—Is certification protection against false imprisonment? and thought that all would be agreed that "any feasible plan for putting an end to what must be called the illegal treatment of lunacy was desirable." Dr. Needham, a Commissioner, thought that the strong point of the whole matter existed in the fact that there was a large amount of illicit treatment of insane people going on.

The question seems to arise, under the circumstances here narrated, whether the evils complained of would not be best met, not by further repressive legislation, but by rendering the whole machinery for reception and treatment into legally and properly constituted asylums, as into other hospitals, as little difficult as possible, a vigilant supervision, of course, being maintained upon all fresh admissions by the medical staff attached to each of them, working loyally and hand in hand with the Commissioners in Lunacy as the supreme authority.

Practically, this state of things already exists, for, under whatever Act a patient is received, once removed from the care of family and friends the medical staffs, supervised by the Lunacy Commissioners, must of necessity assume the full responsibility for any necessary detention. It is hopeless to expect that under any Act, however carefully framed, outcries of illegal detention will not arise from time to time, but such outcries should be at once silenced by the combined testimony of the Commissioners in Lunacy and the medical staffs of the present admirable institutions, both public and private, situated in every county in England.

I am, Sirs, your obedient servant,

FORMERLY A COUNTY ASYLUM SUPERINTENDENT.

THE RECENT PRIMARY FELLOWSHIP EXAMINATION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—Over 70 per cent. of "plucks"! Over eighty of the most hardworking and intelligent of senior medical students and young practitioners told that they do not know anatomy and physiology in a manner to qualify them for responsible and accurate surgery. This is the outcome of the last primary Fellowship examination at the English College. Something is wrong somewhere. To a plain-thinking surgeon of the old school there appear to be three cardinal faults in the examination. *Fault No. 1*—The College has departed from the original scheme of the Fellowship designed by the great leaders in surgical practice and surgical thought of fifty years ago—Brodie, Green, Lawrence,

Digitized by Google

Stanley, South, and such like. And what was the scheme? No one could at that time go in for the Fellowship examination until he was twenty-five years of age, or, in other words, until he had spent a long period in study after obtaining the Membership, which was usually taken at twenty-one or twenty-two. If this rule still held the College would not be besieged by such numbers that in order to restrict them and give a fictitious value to the Fellowship the examination has to be made eliminative by the ingenuity of the questions set. *Fault No. 2.*—Whereas the Fellowship is presumably a mark of special fitness for practising surgery, the questions in anatomy, both in the "written" and in the "*vivâ voce*" examination, have about as much to do with surgery as playing the German flute has to do with learning the German language. The anatomy questions set in the recent examination are about as useless to a surgeon as human ingenuity could devise; and if report does not belie the examination it is deemed ridiculous to suppose that Fellowship anatomy takes any cognisance of practical surgery. *Fault No. 3.*—In physiology candidates are liable to be questioned on any part of this overgrown subject, full as it is of speculation, much of which in a year or two may be cast to the winds, based upon an infinite number of experiments, and specialised to such a degree that probably no individual specialist could pass an examination in the whole range demanded of these young men. None but those possessing an encyclopædic memory can be approximately sure of passing, and the rest, the majority, and probably the most original in thought and observation, have to take their luck in a mere lottery of questions.

To my mind all this has a serious bearing on the future of surgery. These young men, at a time when their minds should be free to devote themselves to clinical study, to original observation, to self-education, and to spontaneous study in directions suggested by their work and opportunities, have to spend their time and waste their brain energy and to dwarf their outlook by devoting themselves to work, half of which no doubt may be of value, whilst the other half is little better than cramming up so many pages of a dictionary. Numbers are tempted to fritter away their energies in passing, or trying to pass, this exacting examination, who never can become surgeons, and who would profit infinitely more by serving as assistants to a general practitioner. The temptation is great, seeing that the F.R.C.S., by sheer dint of the difficulty in obtaining it, has achieved a value far beyond its educational worth.

Let the College have the courage to go back to the original idea of the Fellowship and allow no one to go up for the "primary" examination until he has been qualified for two years. Let the "primary" be an examination really in surgical anatomy, and let it test anatomy learned by dissection, not transcendentalism got up from books. In physiology let the examination be in a carefully selected branch or area of the subject, with a certain option of selection by the candidate.

I am, Sirs, yours faithfully,

"OVER THIRTY YEARS A HOSPITAL SURGEON."

June 25th, 1897.

THE BATTLE OF THE CLUBS.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1711.*)

LEICESTER.

Successful Formation of a Medical Union.—Partial Reforms Obtained.

THE members of the medical profession practising at Leicester have made an effort to deal with the grievances arising from contract or club work. The situation has already been fully described.[2] It will be remembered that the great majority of the population of Leicester belong to medical aid organisations of one sort or another, but that the largest of these institutions is the Leicester and Leicestershire Provident Dispensary. This society was established in 1833, and became a provident institution in 1862. It has now some 39,000 members and employs twenty-six medical men, including some of the most distinguished practitioners in the town. Though the subscriptions paid amount to 4*s.* 4*d.* per annum for adults, the medical men only receive 1*s.* 9½*d.* per annum per member. There are also a great number of benefit societies in Leicester, and several financial companies which combine medical aid with a general insurance business. Shortly after the publication by THE LANCET of the full details concerning the abuses that accompany this contract work the Leicester Medical Society took the initiative, convoked meetings of the entire profession, and a medical union was constituted as a fighting body to deal with all economical questions. It was decided to subdivide the union into sections which were to meet separately. The medical men who worked for benefit societies were to form one section, those who were employed by insurance companies another section, and the twenty-six medical men who belonged to the Provident Dispensary formed another section. It is doubtful whether this was a wise course to follow. The interests and the circumstances of each group certainly differed greatly, and time might be economised by discussing separately these various matters. But, on the other hand, the prime object of a union is to engender a strong sense of solidarity between all members of the profession, however the position of individuals or of groups of individuals may differ. Medical men cannot be too well informed as to the position, the difficulties, and the opinions of other medical men. In Leicester there is considerable hostility felt against the medical staff of the Provident Dispensary. There is a tendency to look upon them as privileged individuals; and therefore their first object should have been not to meet privately, but, on the contrary, to seek to associate on every possible occasion with the other medical men so as to dispel any and every existing misunderstanding.

When the union was formed nearly every medical man in the town joined, but the sectional meetings tended to disunion. Each section strove for its own interests, instead of coming to a common agreement to commence by fighting on the line of least resistance. In fact, the true sense of unionism has not yet arisen; the members showed too much anxiety to better their own position instead of ascertaining which was the worst case or the weakest point and fighting that first. With from eighty to ninety medical men in union everything was possible had better statesmanship and greater discipline been displayed. So strong was the union that the clubs and societies met its representatives in a most conciliatory manner. The Provident Dispensary was approached and an increase of payment for the medical staff equal to about 30 per cent. demanded. Thereupon a few of the dispensary medical officers conceived the idea that the main object of the union was to attack the dispensary and that the other medical men were desirous of shattering that institution so as to pick up the fragments. The majority, on the contrary, had a better opinion, and were convinced that this was not the case. On the other hand, it could very well be urged that the dispensary medical officers were not actuated by altruistic motives. Instead of receiving 1*s.* 9*d.* per member per annum they wanted 2*s.* 6*d.* This was all very well in its way, but it touched no general principle. Such a request, if granted, would improve the financial position of the dispensary staff, but it would not do away with any of the grievances that affect the profession as a whole. The point of common interest to all is the wage limit. Doubtless, to the dispensary medical officer it is very important that out of the 4*s* 4*d.* paid by the members he should receive 2*s.* 6*d.* instead of 1*s.* 9*d.*; but what effect would this have on the other members of the profession and on the public at large? So long as a patient is not able to afford more than 4*s.* 4*d.* a year for medical attendance, the sub-division of that sum between the collectors and organisers of the dispensary and the medical staff of the dispensary is altogether a secondary question. What interests the medical profession at large is that they should not lose their patients by persons being allowed to join the dispensary when they are in so good a financial position as to be able to pay the ordinary medical fees. The public, on its side, is interested in seeing that the high-standing and efficiency of the medical profession shall be maintained and not compromised as at present by excessive club practice and the careless, hasty work it involves. The dispensary medical officers should then have demanded on behalf of the profession at large and of the entire public, that the abuse of the dispensary should be checked. When this had been secured by the

[1] A reprint of the previous articles on the above subject has been published in book form entitled, "The Battle of the Clubs," and can be obtained from THE LANCET Office, price 1*s.*

[2] See The Battle of the Clubs, THE LANCET, Feb. 15th and 22nd, 1896, and page 123 of the reprint.

Digitized by Google

imposition of a strict wage limit it would have been time enough to discuss the sub-division of the 4*s*. 4*d*.

Unfortunately this was not done. The dispensary medical staff did not stand to the wage limit. The dispensary committee said they were ready to expel anyone whom the medical men might denounce, and argued that as the medical men went into the rooms of the patients they were best able to tell whether the members were able or not to pay proper fees. But this is not the case—first, because the vast majority of patients are out-patients; and secondly, because medical men can ill afford to make themselves unpopular in the town by causing people to be expelled from the societies to which they have subscribed. Nevertheless, the Dispensary Committee was on the point of yielding when some of the dispensary medical men became alarmed, and this rendered the position of the majority untenable. They were therefore obliged to accept the suggested compromise. The share of the 4*s*. 4*d*. to be paid to the medical staff has consequently been raised from 1*s*. 9*d*. to 2*s*. 2*d*. instead of 2*s*. 6*d*. as demanded. This is equal to an increase of about 15 per cent. instead of the 30 per cent. which had been claimed. Then the subscriptions for family tickets will be raised from 3*d*. to 3½*d*., instead of 4*d*. as proposed. Further, the medical staff will now obtain a guinea fee for first accouchements and 15*s*. for second accouchements. They are also to receive 7*s*. 6*d*. for miscarriages under three months, whereas formerly no extra allowance was made for these latter cases. Altogether, it is calculated that the medical staff of the Leicester Provident Dispensary will receive between them something like £600 per annum more than they formerly obtained.

Inspired by the example of the Provident Dispensary and alarmed by the strength of the Medical Union, the Foresters' benefit society also made some concessions. They raised their scale of pay to that of the Oddfellows—namely, 2*s*. 9*d*. to all medical men and 1*s*. 3*d*. to the dispensing chemists per member. Had the dispensary medical officers held out for an increase to 4*d*. for the family tickets the benefit societies would also have moved in this respect; but as the increase obtained only amounted to a halfpenny the benefit societies did not think it worth while to make any alteration. In all this, however, it is encouraging to note that some solid advantages have been acquired. The agitation has also served to make the grievances of the medical profession known to the general public and has awakened the public conscience. A great many respectable people have now withdrawn from their clubs and have become private patients. This is a material benefit to the profession and an advantage to those who are really entitled to belong to clubs. It is also easier now for medical men to call the attention of well-to-do club and dispensary patients to the fact that they ought not to belong to such institutions, but should become private patients. In a word, in spite of mismanagement, enough has been done to conclusively demonstrate the advantage of unionism. The partial failure which the Leicester Medical Union has experienced should not, therefore, discourage its members. Instead of harping on this less pleasant side of the picture it is better to think of the partial success which has been achieved. The solid advantages gained should stimulate the members of the union to redoubled efforts. Taught by experience, they ought now to be able to perfect their organisation and improve its ethical basis so as to imbue its members with the true spirit of unionism, and thus ensure for their next effort, not a partial, but a complete success.

THE DWELLINGS IN BOMBAY.

(FROM A CORRESPONDENT.)

ALTHOUGH scientific research has not yet recognised the plague bacillus in the air, in water, or in food, and although its existence in the dejecta of the human body is still contested, Bombay has made an important step towards better sanitary conditions, for whilst deaths from plague still continue, the death-rate has fallen below the normal line, and few people can doubt that the cleansing that has been carried out so energetically during the past few months in the streets and dwellings of Bombay has had an important influence in diminishing the mortality. The magnificent main thoroughfares and public buildings of the city produce a totally false impression on the mind of the visitor who may pass a few days or weeks of the cold season in some hotel or private bungalow, the latter an isolated house in one of the best quarters of Bombay. There is nothing to attract him to the scores of miles of dirty, squalid streets or to the filthy houses which line them. It is, however, the class which lives in such quarters whose habits give the sanitary note to Bombay. It includes all Indian domestic servants; and until the Plague Commission, with its military president, by a sanitary crusade such as has no parallel in the history of India took action, the above class triumphed over every effort that was made by the municipality to improve its condition. It is true that the municipal effort did not take a very energetic form. Conservancy, drainage, and water-supply were provided, but the by-laws of the Municipal Act were not enforced, and the people did not give that personal assistance to the authorities without which no sanitary system can possibly succeed. Filth is still thrown with impunity upon sanitary inspectors from upper windows in narrow streets. A few days ago a parcel of nightsoil in paper was thrown by an office messenger from the window of a consulate into the street, and recently a bucket of water that had washed a floor and was of the colour of sewage was thrown from a balcony of the best hotel into the principal street of Bombay. These examples will illustrate the influence of the class already mentioned in the interest of disorder. Its members are not particular how they live so long as the cost is low, and as their sense of smell was dulled ages ago to all ordinary odours they are, as a rule, quite indifferent to their surroundings. Such people are very easy-going tenants, a fact that house proprietors quickly recognise, and it may safely be stated that there is no place so dark or unsavory that it cannot find a tenant. Much of what is known as the Fort and the City was built before the creation of the municipality, and before the ideas of ventilation or perflation had any place in the schemes of house building. The dominant idea of the landlord was to get the utmost accommodation upon his land, and the four-storey house with 10 to 30 ft. of frontage and a depth of 100 ft., flanked on each side by a gully not more than from 2 to 2½ ft. wide, may now be found in hundreds. The gully is, of course, an open sewer into which all house refuse is thrown, including nightsoil, which frequently adheres to the opposite walls. The air supply and light of rooms opening from the gully come through that channel. The common stair of such a house is dark and has not even a skylight; there is no exit to the roof, which is tiled, and thus the only possible ventilating shaft is inoperative. The common stair, being common property, is never cleaned; no Indian proprietor considers this to be any part of his duty. Such a house consists of a series of rooms, each of which may at any time contain a family. The only permanent fittings are a *nahni* or sink, raised a few inches above the floor and discharging through the wall into a downtake pipe which terminates at the gully, and also a low platform of masonry or mud to serve as a fireplace for cooking. There is no chimney, and wood fuel or cowdung cakes are used twice a day. The interior is thus blackened in a short time and remains black. It is the same if a special room is set apart for cooking, or even if there is a cookhouse adjoining; there is no chimney. The *nahni* is intended to receive sulliage only, but it is regularly used as a latrine, particularly by women and children; and as air currents pass frequently at night from the discharge pipes into the rooms, the latter being warmer than the night air, much sickness has resulted from this cause. Wall syphons were fixed by the municipality in great numbers to the downtake pipes with a view to arrest the foul air currents, but the people persisted in putting sand, leaves (off which they eat), rags, and other solid matter into the pipes, and a staff of men was and is kept constantly employed cleansing them. There is no penalty for blocking a syphon. If no syphons are used, the descent of a small quantity of liquid from an upper floor drives foul gases from the downtake pipe into the rooms below. The indigenous channel for waste water in a storeyed house is an open groove or gutter down the face of the wall; it is common in Lucknow and Cawnpore, and its advocates say that being open to the sun and air there is no putrefaction within it as is the case in all downtake pipes. During the session of the "House Connections Committee" appointed by the corporation to inquire into the best form of connection between dwellings and sewers I

Digitized by Google

made certain experiments to ascertain the effect of falling water in vertical downtake pipes and also the effect of flushes to remove obstructions in wall syphons. The same instrument was used as in the experiments on gas pressure in the sewers, described in a previous article.[1] The experiment on the effect of falling water in a vertical downtake pipe was made at a three-storey house. The pipe was three inches in diameter at the third storey and five inches at the two lower storeys. It was open at the top of the house and sealed at the foot. The gauge was attached above the seal, and there were no wall syphons. The compression of the air at the foot of the pipe varied with the quantity of water thrown down, and with the time it took to disappear from the third storey *nahni*. Twenty pounds of water discharged in twenty seconds produced a maximum pressure of 0·88 in.; 10 lb. in sixteen seconds produced a pressure of 0·16 in. Each discharge caused a whiff of foul air to enter the lower storeys through the *nahni*. A 2½ in. pipe was next fixed to a wall to represent the height of a single storey. It was sealed at the foot and had a funnel at the top, 13 ft. 10 in. above the seal. The gauge was fixed 2 ft. above the seal. One quart thrown down the funnel produced a maximum pressure equal to 0·64 in. of water. Two quarts produced an effect almost similar, and four quarts produced an increased effect. The pressure corresponded to velocities of 26, 26, and 29 miles per hour.

Experiments to ascertain the rate of current of water required to carry all solid matter through a wall syphon, or to wash it out if it became blocked, showed that fragments of brick were washed out from a 2½ in. syphon with water flowing at a rate not less than 77·76 ft. per minute. Road metal (macadam) was washed out from a 4 in. syphon with a current at the rate of 82 ft. per minute. This syphon was then choked with gravel, sand, mud, leaves, and coir yarn, rammed in with a hammer shaft. Two flushes of three gallons each cleansed the syphon. The flushes were applied in five and five and a half seconds. Although it was clearly demonstrated that wall syphons could be cleansed by small flushes of water applied suddenly, the construction of the *nahni* precludes the possibility of a rapid flush. If fine gratings are placed on the *nahni* outlet they are broken by the people. The wall syphon is therefore a failure in Bombay because the people will not modify their habits and because municipal rules have not been enforced. The state of the atmosphere of a room which is kitchen, latrine, and bedroom all in one in a city the mean temperature of which is 79·13° F., and the shade temperature of which at the time of writing is 89°, with a relative humidity of 71 per cent., may be imagined. Only people whose sense of smell is very defective could tolerate it. Within doors the people are nearly naked; they are thus able to bear an amount of heat and an absence of ventilation that would otherwise be intolerable.

Many of the wealthy Indians have their dwellings in narrow, crowded streets, where houses reach a height of six storeys, and as rich and poor live in close proximity the result is a very high mortality. A scarcity of houses and high rents have given a permanent character to overcrowding, and should any of the schemes recently discussed for the extension of the city be realised it will probably be very difficult to overcome the habit among people whose ideas of domestic comfort would not be understood by any European. A scheme is at present in course of development by one of the leading mill managers of Bombay to provide better house accommodation for mill coolies, whose dwellings have recently been destroyed in considerable numbers as unfit for habitation. The new dwelling is of corrugated sheet-iron, each room is 12 ft. by 10 ft. with two windows, a door, and a verandah. There is a ridge ventilator and an opening below the eaves, a fireplace, and a *nahni*. It is intended to charge about one-third of the usual rent for these *chawls*. Five hundred of them are to be ready for occupation before the end of this month. The Bombay Port Trust is also building a number of well-designed labourers' dwellings, which are much needed. Hundreds of the dock labourers have no dwelling of any kind, sleeping in the streets all through the fair season and under the shop-fronts in the bazaars during the rains.

There is ample experience to prove that the dwellings of the labouring classes should have no *nahni* within the living-rooms and no water-supply indoors. They will tie any water-tap open, and let it run night and day, regardless if it produces a swamp at their door, and they will use the *nahni* for natural purposes in spite of every warning. Public latrines, well designed and well kept, are the only suitable provision for them. Their constant endeavour is to maintain the habits of the jungle while enjoying the good pay and the excitements of a large city.

The approaching monsoon and the necessity for careful legislation on the subject have put a stop for the moment to projects of wholesale alterations among the solid mass of hovels in which many thousands of the people live and die. All through the dry season they sleep in the streets, on the side-walks, but in the rains they must go indoors. The small ratio which the street area bears to that of the houses indicates that all the roofs should be flat for the sake of the healthy open-air space they would provide in congested quarters. The only remedy, short of pulling them down, that could be applied to the unventilated and unlighted blocks of dwellings would be to cut shafts through them from to top bottom of a diameter based on the height. The shaft might be used as a stairway. The distance from the outer walls to the shaft could be determined on well-known rules. Europeans, although their death-rate has been actually less during the plague than before, are awakening to the anomaly of having lived for 236 years—since the Island of Bombay was ceded—in houses utterly destitute of systematic ventilation and built by and for nations having very few of the conveniences required by Europeans. Few people arriving in Bombay from London are aware that the difference in mean temperature between the two places is 30° F., nearly one-third of the temperature of the human body; or that the principal difference between comfort and discomfort in the tropics consists in the rate at which the air in contact with their bodies is changed. The only kind of house they can hire is full of doors and windows, but has not a single opening through its roof, which extends over wide verandahs; and although pleasant during a light breeze, it is hot and stuffy during the frequent periods of dead calm. In a dead calm, which occurs every night, the only natural current possible is that due to the difference of temperature between the building and the outer air, and it can only work usefully through large openings in the roof. This arrangement is only feasible in single-storey houses. It is possible to use the sun's heat directly to produce a ventilating current through a roof. In Cawnpore I fixed a light sheet-iron chimney 22 in. square and 10 ft. high on the flat roof of a single-storey bungalow; another opening 22 in. square was made into the same room but at the opposite end. The influence of the sun's heat on the black iron heated the column of air within it 16° F. and produced a current equal to 133 ft. per minute. The circulation of air through the room by the roof openings was 26,853 cubic feet per hour, and it was free from the smell of moist earth that is often noticed in air coming through doorways from a garden. The circulation continued night and day varying in velocity and direction but always producing a sense of freshness unknown before in the house. The range of temperature and of relative humidity of the air in India produce changes to which the European constitution accommodates itself with difficulty, for the escape of surplus heat from the body must continue with unfailing regularity in all weathers. Agitation of the air, such as is obtained by the aid of a punkah, affords some relief, but is only a partial remedy. The constant renewal of the air from some pure source is one of the chief essentials of healthy life in India. In a city like Bombay it can only be realised by the aid of special mechanism, but, properly carried out, it offers a solution to the problem of providing cheap and healthy dwellings for Europeans. The high cost of land in Bombay and the excellent foundations that are to be found in and about the city are both favourable to the construction of buildings of not less than six or eight storeys, or one hundred feet high. At this elevation the air is very pure and free from insects of all kinds; it also contains very little dust, but as the wind is quite unreliable for the purposes of ventilation in Bombay a constant supply of air from the roof would have to be provided by means of a fan and probably an oil motor, and distributed through every room in the building. The upper part of the corridor, separated by a partition, would serve as a convenient air-duct to supply each room, and in this manner the ground floor would have the same advantages as the top floor, and the tenants at all times would be able to depend on a constant and uniform supply of fresh air. The restorative value of being able to sleep under such conditions cannot be

[1] THE LANCET, March 27th, 1897, p. 917.

Digitized by Google

over-estimated. The superior cooling power of the air, even at a small distance from the ground, was proved at Cawnpore at the time of some ventilation experiments. Two similar porous water-bottles were filled with water and placed one on the ground and the other on a parapet wall twenty-five feet above the ground at sunset. In the morning at 5 30 the temperature of the water on the ground was 72° F., and that on the parapet wall 68° F. A house ventilated with air taken at a hundred feet above the ground would accumulate very little dust; and as a fan engine would work well with a dynamo, electric lights might be combined with the ventilating apparatus. With regard to lifts, it is probable that the cheap manual labour of Bombay would provide a satisfactory motive power with a simpler mechanism than any of the steam and hydraulic lifts at present in use.

Once the circulation of air is assured health and comfort might be enjoyed in much smaller rooms than are now considered necessary, and in this way rents might be kept at a moderate figure; and if the details of construction were carefully adapted to European requirements the number of native domestics might be cut down to the lowest figure. This is most important, as each servant is a living nucleus of dirt and disorder unless under constant supervision. Each year as soon as the rains are over a considerable area of open park ground adjoining the Fort is covered with tents by Europeans who cannot find suitable houses. This is an annual reminder of the inadequacy of house accommodation such as has just been proposed. We must not, however, look to the native capitalists to provide such buildings. It would be unreasonable; and even were they to attempt it they would certainly ruin the internal arrangements by meddling. Such a project offers an excellent investment for English capital, as it would meet the urgent need of middle-class Europeans in a city which has for long been noted for its high rents and the abnormal profits of its house proprietors.

Bombay, June 3rd, 1897.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

THE fifteenth annual meeting of the German Congress of Internal Medicine was held in Berlin from June 9th to June 12th. An abstract of the President's address has already appeared in THE LANCET of June 19th (page 1713). On the conclusion of this inaugural discourse several speakers delivered addresses welcoming the Congress to Berlin, after which the practical work of the meeting commenced.

Chronic Rheumatism and its Treatment.

Professor Baumler (Freiburg) read a paper on Chronic Rheumatism, in which he said that the name of rheumatism has been applied to the most dissimilar pathological conditions. Properly speaking, only the chronic form of polyarticular rheumatism should have this name, whilst the other monarticular forms caused by mechanical injuries, gonorrhœa, &c., should be distinguished as traumatic arthritis, gonorrhœal arthritis, &c. The so-called "arthritis deformans" is only a progressive and advanced form of chronic polyarticular rheumatism. The etiology of the disease remains very obscure; atmospheric influence undoubtedly is of great importance, though this is denied by some physicians. The term "arthritis pauperum" is a misnomer, as the disease is not confined to the poor, but is frequent in well-to-do people also. Women are more easily affected than men; Dr. Ord has therefore suggested that the disease may be due to reflex irritation originating in the reproductive organs, but an infection originating in these organs and propagated from them into the joints would be a more probable explanation. Several physicians have suggested, chiefly on bacteriological grounds, that rheumatic polyarthritis might be an infectious disease; in 1892 Schüller discovered a bacillus in the arthritic joints; in 1894 Bannatyne and Wohlmann found a bacillus in the fluid obtained by puncturing a joint; and Blaxall has even succeeded in cultivating the bacillus.—Professor Ott (Prague) pointed out that any acute inflammation of the joints should at the outset be treated in an antiphlogistic way. The patient should stay in bed, the joints should be kept motionless, and opiates and salicylate compounds should be given. When the acute symptoms have disappeared baths are very useful. Ordinary baths are indicated when nervous irritability accompanies the affection of the joints, the water of saline and sulphurous springs is to be preferred in other cases, whilst mud baths prove useful in more torpid forms. Sand baths and Russian baths, although useful for robust persons, must not be employed for delicate or anæmic patients. Massage, electricity, and mechanical exercises are of great use in ankylosis. The general state of the patient should never be neglected, and a nourishing diet, together with iron and other roborant medicines, should be prescribed in chronic cases.—In the ensuing discussion Dr. Chvostek (Vienna) denied that bacilli are present in chronic rheumatism. He has found that the fluid in arthritic joints is sterile.—Dr. Singer (Vienna) said that he had observed staphylococci and streptococci in the urine of patients suffering from acute rheumatism, and that some micrococci were found in three necropsies. He was of opinion that streptococci and staphylococci are the causes of acute rheumatism, and argued that the acute swellings of the joints which are a well-known symptom in pyæmic affections lend support to his views.—Professor Schüller (Berlin) recommended the injection of iodoform mixed with guaiacol.—Dr. V. Noorden (Frankfurt) said that he had tried the so-called lemon cure. Theoretically there was no reason for expecting any influence on metabolism, but temporary improvement nevertheless sometimes occurred.

Epilepsy.

Professor Unverricht (Magdeburg) read a paper on Epilepsy, in which he said that he would confine his remarks to the pathology of this disease and would abstain from therapeutical questions. Experiments on animals had led him to believe that the cerebral cortex is in every instance the region from which the fit derives both its origin and its perpetuation; he therefore found himself in opposition to Kussmaul and Nothnagel, who held that an epileptic fit originated in an irritation of the medulla oblongata. The epileptic attack caused by an electric irritation of the cortex of animals consists of two parts: first, the muscles of one side and then those of the other side begin to contract. If the fits follow one another very quickly clonic convulsions of the whole muscular system occur, just as in genuine epilepsy. When parts of the motor region of the brain are removed the muscles actuated by these centres no longer take part in the convulsions; if one side of the brain is completely removed the convulsions are hemilateral only. With respect to the circulation he has discovered that during the epileptic fit the pulse is at first accelerated and the blood-pressure increased; in the second stage the pulse is retarded, in the third stage it is again accelerated, whilst in the fourth stage it returns to the normal. Professor Unverricht pointed out that there is no difference between cortical epilepsy and genuine epilepsy; they are each of them only different degrees of the same illness, and when the anatomical conditions of the fits are better known the word "epilepsy" will become a more distinctive term, just as it is customary to speak of alcoholic poisoning and lead poisoning or syphilitic and uræmic convulsions. In the course of the paper it was mentioned that there are 100,000 epileptics in Germany.—In the discussion Professor Flechsig (Leipzig) remarked that bromine is retained in the organism for a considerable period. Of 80 grammes given within eight days, 41 grammes were retained; and of 24 grammes within three days, 21·5 grammes were retained. After a certain time the organism is saturated with bromine. When the bromide employed has ceased to be efficacious it must be combined with opiates.—Professor Binswanger (Jena) and Professor Jolly (Berlin), in opposition to Professor Unverricht, maintained that epilepsy might also be induced by subcortical irritation.

Etiological Therapeutics.

Professor Behring (Marburg) said that the treatment of disease with drugs had failed because it was based on experiments made on healthy animals. Allopaths err when they endeavour to correct symptoms, and their theory "*contraria contrariis*" is not more reasonable than the "*similia similibus*" of the homœopaths. Cellular pathology has proved useless as far as therapeutics are concerned. Natural therapeutic processes include—(1) phagocytosis; (2) removal of the virus by the perspiration, the urine, and the fæces; and (3) the protection afforded by the epidermis

Digitized by Google

and the epithelium. Etiological therapeutics are based upon the circumstance that the animal organism, when invaded by certain kinds of pathogenic virus, has the power of forming antidotes which not only render the particular individual immune against such virus, but are also available for administration to other individuals. The antitoxic power present in the organism of highly immunised animals is specially concentrated in the blood serum. The antitoxins hitherto discovered are not all of similar efficacy. Diphtheria antitoxin has been clearly proved to be successful, but tetanus antitoxin sometimes fails, owing to the fact that it is not usually kept in hospitals and consequently is not at hand for sufficiently early administration. Marmorek's anti-streptococcic serum is very doubtful, whilst Maragliano's tuberculosis serum contains no antitoxin at all. The antitoxins themselves are innocuous, and the removal of the causes of such undesirable symptoms as urticaria, &c., is a mere matter of improving the practical details of the manufacture. All attempts to produce a chemically pure antitoxin have failed, and must necessarily do so, owing to the fact that antitoxin is not a definite chemical compound, but is rather a quality inherent in certain albuminous substances, somewhat as magnetism is in iron. Passive immunisation by means of antitoxin is preferable to active immunisation by direct toxins. Experiments are at present being made in the hope of discovering a method of prolonging the immunising power of antitoxins. When the virus of the disease is unknown, as in the case of septicæmia, the production of antitoxin is impracticable. Professor Behring finally announced that he was carrying on researches with the view of discovering a new anti-tuberculous serum. Alluding to Professor Koch's new tuberculin, he declared it to be very valuable for the lower animals—in fact, more suitable for them than for the human subject. In concluding his address Professor Behring remarked that the prophecy that bacteriology would have no application or utility in the practice of medicine had been disproved by the introduction of the antitoxin treatment.

Graves's Disease.

Professor Eulenburg (Berlin) pointed out that the three leading symptoms of Graves's disease—thyroid enlargement, exophthalmos, and cardiac palpitation—have been supplemented in the course of time by a series of other phenomena. He mentioned specially the ophthalmic conditions described by Graefe, Stellwag, and Moebius, the so-called Marie's tremor, the diminished resistance to galvanic currents observed by Charcot, Vigouroux, and himself, the special glycosuria discovered by Chvostek, and finally all those neurasthenic and hysteric troubles which are so characteristic of this affection. Not every one of those symptoms is present in each instance of Graves's disease. There are cases where some one or other of them is but little developed or disappears during the course of the disease. Three etiological theories of Graves's disease have been advanced—the hæmatogenic, the neurogenic, and the thyreogenic. The first-mentioned is based on the prevalence of the disease among females, its commencement during adolescence, its connexion with dysmenorrhœa, and the beneficial effect of pregnancy observed in some instances. Discussing the neurogenic theory Professor Eulenburg said that all attempts to localise the affection in either the vagus or the sympathetic nerve have been unsuccessful, for its clinical symptoms, its development after severe injury, and its connexion with other constitutional neuroses, such as epilepsy, hemicrania, chorea, and diabetes, prove that the disease is a constitutional neurosis. Gauthier was the first to suggest an alteration of the chemical composition of the thyroid gland as a cause of Graves's disease, and Moebius drew attention to the contrast between its symptoms and those of myxœdema. Tachycardia, exophthalmos, mental excitement, and emaciation were caused apparently by hypertrophy, and slowness of the pulse, mental apathy, and obesity by atrophy of the thyroid gland. The gland undergoes alteration in function as well as in size, and it probably produces a toxic substance which acts on all the parts of the nervous system. On the subject of treatment Professor Eulenburg said that the hæmatogenic theory required the administration of remedies directed against anæmia and chlorosis, whilst the neurogenic theory suggested the use of electrical, psychical, dietetic, climatic, and hydropathic methods. The supporters of the modern thyreogenic theory have recommended thyroidectomy combined with the internal use of thyroid preparations, but this operation should be reserved for cases where the local symptoms preponderate, and it is found that general treatment gives very favourable results with many patients.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The New Hospital.

As the nearness of the time approaches considerable interest is being evoked in the advent of Prince and Princess Christian to open the new hospital on July 7th. Additional zest is given to the public enthusiasm by the liberality of the licensed brewers who have arranged for the decorations which lately adorned St. James's-street, London, to be transferred to the main street of Birmingham for this opening ceremony. A few distinguished persons have been invited by the Lord Mayor of the city to meet their Royal Highnesses, whose stay will be short, and whose duties will be impressive and important.

Mason College and the Diagnosis of Diphtheria.

The health committee of the town council have made an important arrangement with the authorities of Mason College for the bacteriological examination of the products in cases of suspected diphtheria. By placing also a supply of serum for treatment at the disposal of any medical practitioner without fee an opportunity is given for the early treatment of this malady which cannot fail to afford the best chances of dealing with it in the light of the most advanced cientific discoveries.

General Institution for the Blind.

The fiftieth annual meeting of this institution was held on June 16th. The report showed that the total number of blind people who had directly benefited during the year was 518. The turnover for the sale of goods had realised over £3000, while the deficiency in income was £487. Instances were given of the value and character of the training employed, and an earnest appeal was made for more funds.

Royal Institution for the Deaf and Dumb.

Not less interesting was the annual meeting of the friends of this institution, when the opening of the new buildings with extensive improvements was declared by the Hon. Somerset Calthorpe. One hundred and eighty pupils are now educated in lip language, whose progress was markedly illustrated in the course of the meeting. Special attention is paid to physical training and various industrial pursuits, so much as to call forth high praise from the Government inspector and experts, whose testimony was appended to the report.

Government Grant to Mason College.

The additional grant of £2700 to Mason College made by the Chancellor of the Exchequer under a recent report has given rise to much satisfaction. Opportunities will thus be given for advanced work and research, which will promote the efficiency of the college in a marked degree. Money could not be better spent than in such a direction in the cause of education.

June 29th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Health of Liverpool.

THE deaths registered in the city during the week ending June 19th were 244, making a rate of total mortality equal to 19·7 annually per 1000 of the population. Of the total deaths 110 were of children below five years of age, and of these 64 were of infants below one year. In view of the prevalence of diarrhœa, which is so common at this season among children and infants, especially of the lower classes, the medical officer submitted a memorandum of precautions. Dr. Hope lays special stress on cleanliness of person, clothing, and surroundings. All water required for drinking purposes should be taken direct from a main, but if from a cistern it should be boiled before using. No filth or dirt should be allowed to accumulate within or near the house; the ash-pit should be frequently emptied, no slop water should be thrown into it, and animal

Digitized by Google

and vegetable refuse should be burned. Windows should be kept open every day for some hours. The water-closet should be frequently flushed. Other important directions as regards food are also given. Measles still continues prevalent in the city.

The Sanitary Condition of Birkenhead.

Dr. Marsden, the medical officer of health of Birkenhead, has issued his annual report on the sanitary condition of the county borough of Birkenhead. He explains that each succeeding report deals with the various agencies which are acting deleteriously upon the public health, and which tend in many ways to reduce the vitality of the community, and thus act injuriously on the well-being of the town. For the purpose of awakening sympathy with the agencies at present in operation for the improvement of these conditions, publicity is given in each successive report to the weak spots in the administration of the borough and to the unnecessary waste of life which is constantly going on and which it is the object of the report to disclose. Dr. Marsden again draws attention to the unsatisfactory homes of the working classes and to the condition of the sewerage in the older parts of the borough, with the object of stirring up the municipal authority to afford facilities for ameliorating this state of things. Dr. Marsden goes on to say that the public health of the borough during the year 1896 has been satisfactory in every way. The borough has an area of 3849½ acres—a little more than six square miles—with an estimated population of 108,818. The death-rate in 1896 was 19·44 per 1000, compared with 19·90 in 1895. The zymotic death-rate was 3·32 per 1000. In the appendix to the report are tabular statements of the year's mortality within the borough, classified as to the disease, ages, and localities, a weekly register of deaths and of meteorological results, and a monthly summary of deaths from all causes. Dr. Marsden also deals with illegitimate children, of whom 39·2 per cent. died within twelve months of birth; these numbers are higher by 3 per cent. than the rate of mortality of the previous year. Dr. Marsden also refers to certain "insanitary areas" within the borough, and hopes for improvement in their condition.

Liverpool and Ormskirk Jubilee Commemoration Funds.

Of the £30,000 necessary to complete the augmentation of the Liverpool district nursing scheme, alluded to in a former number of THE LANCET, upwards of £7000 are still required, the amounts received to date being £22,970 10*s.* 8*d.* It is also pleasing to record that Ormskirk is not to be behindhand in the matter of providing nurses for the benefit of the sick poor of that district in their own homes; it is proposed in commemoration of the Jubilee to make accommodation for five or six nurses in the enlarged Ormskirk Cottage Hospital, who services will be given free of charge to those who, by reason of their poverty, cannot afford to pay for them.

Clerical Victims of Typhus Fever in 1847.

A service was held a fortnight ago in commemoration of the ten Roman Catholic clergymen who died from typhus fever within six months of each other in the discharge of their religious duties in 1847, when that disease broke out among the Irish immigrants who flocked to Liverpool owing to the famine in Ireland. The numbers arriving from Ireland were so large that the lower parts of the city became greatly overcrowded, typhus fever spreading with alarming rapidity and being followed by a high rate of mortality. Monsignor Nugent, the well-known Liverpool philanthropist, preached the sermon and described from personal recollection the sufferings and privations of the poor of Liverpool during that dreadful time. He also dwelt on the heroic conduct and self-sacrifice of the victims whose memory they were then met to honour. A comparison of the Liverpool of the year 1847 with that of to-day affords an instructive object lesson; in the former year were rows of streets with fœtid courts enclosed, to the consequent exclusion of light and fresh air, which are now occupied by healthy artisans' dwellings with salubrious surroundings. The contrast is, indeed, striking, and is a matter for much thankfulness and congratulation. In this connexion it may be interesting to note that typhus fever has been almost stamped out in Liverpool, the disease being now comparatively rare.

New City Magistrates.

Dr. Thomas Clarke and Dr. William Cross have been placed on the Commission of the Peace for the city of Liverpool.

June 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Typhus Fever in Ireland.

IT was thought for the last few years that typhus fever, for a long time a sanitary disgrace to Ireland, had practically disappeared. Some cases have, however, been recently admitted to the Cork-street Fever Hospital from Dublin. In Athlone Union typhus fever has broken out in the Castlesampson division, and five deaths have already been recorded. The prevalence of this fever in Belmullet Union was the subject of a question in the House of Commons on June 28th.

The Jubilee Nursing Scheme in Ireland.

The movement to supply nurses to take charge of the sick poor in their own homes is certain to prove a success. Since the influential meeting held in Dublin last month a number of subscriptions have been received, including £100 from the Roman Catholic Archbishop and £500 from Sir John Arnott.

Mercer's Hospital, Dublin.

As was mentioned many weeks ago the candidates for the vacancies on the staff of this hospital were obliged to enter their names before June 18th. Some twenty candidates have applied, including one well-known medical man—viz., the present master of the Coombe Hospital. Of the members of the staff recently dismissed by the board Dr. M. Ward is the only one to be found among the candidates. Dr. T. Mason will probably be given a consultant position in connexion with the hospital. Mr. O'Grady and Mr. Auchinleck have not applied, and intend to contest at law the power of the board of governors to dismiss their medical staff. The election will take place on July 6th, when it is proposed to elect three physicians and four surgeons.

Irish University Education.

The Irish Roman Catholic Bishops have just issued an important statement on this question. They say: 1. With regard to the constitution of the governing body of a Catholic University that if in other respects it is properly constituted they do not ask for a preponderance, or even an equality, in the number of ecclesiastics upon it, but are prepared to accept a majority of laymen. 2. As to theological teaching, they accept Mr. Morley's suggestion that a theological faculty should not be excluded from the Catholic University provided that the chairs of the faculty are not endowed out of public funds. They are prepared to agree that the moneys voted by Parliament shall be applied exclusively to the teaching of secular knowledge. 3. As to the appointment and removal of professors they think that all reasonable protection for the position of the professor may be met by submitting questions concerning him to the decision of a strong and well-chosen board of visitors, in whose independence and judicial character all parties would have confidence. 4. As to the application of the University of Dublin Tests Act of 1873 they say that, with some modification in the Act in the sense of the English Acts of 1871 and the Oxford and Cambridge Acts of 1877, they have no objection to the opening up of the degrees, honours, and emoluments of the University to all comers. They ask not for a college, but for the foundation of a university.

June 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Method of Treating Aneurysms.

M. LANCEREAUX recently showed at the Academy of Medicine a patient the subject of an enormous dissecting aneurysm of the aorta, which he had treated successfully by a new method introduced by M. Dastre. This method consists in the injection into the veins of a sterilised solution of gelatin, of a strength of 1 per cent. The doses vary in quantity and are continued for some days. Cure is brought about by the formation of a clot. This procedure is absolutely harmless, and would appear to be of great service in these cases of deep-lying aneurysms which are not amenable to surgical treatment.

Digitized by Google

Deaths under Chloroform.

The daily press is making a great to-do about two cases of death which have recently occurred in the hospitals during the administration of chloroform. The first fatality occurred in an infant, a year old, at the Trousseau Hospital, where the child had been anæsthetised for the purpose of a congenital club foot being operated upon. Heart failure set in and the child died despite all the efforts made to restore him, including a tracheotomy. The second case was that of a man, aged thirty years, who was anæsthetised at the Tenon Hospital for the purpose of having a badly set fracture of the leg rectified. The police officials have commenced an inquiry as to the responsibility of the medical men in these two cases.

An Explosion at the Sorbonne.

A rather grave accident happened on the evening of June 28th during one of a course of lectures given by M. de Lacaze-Duthiers, Professor of Zoology, Comparative Anatomy, and Physiology at the Paris Faculty of Science. Just as M. Lanceplaine, who is nephew and prosector to the professor, was arranging the lantern so as to throw some micro-photographs upon the screen a violent explosion occurred and the fragments of the lamp wounded M. Lanceplaine in the face. A splinter of glass from the manometer also wounded another demonstrator, M. Brumpt, in the leg. Care had been taken not to use the vapour of ether in the lamp, and probably the explosion was due to the defective condition of the manometer. It is only by a happy accident that none of the students present were hurt, for the débris was scattered as far as the topmost rows of seats in the theatre. M. Brumpt is going on as well as possible, but M. Lanceplaine is seriously wounded in the right eye, and the medical men in attendance say it will be some days before they can definitely pronounce as to the result.

Death of M. Schützenberger.

At the last meeting of the Academy of Sciences signs of mourning were apparent owing to the death of M. Schützenberger, the celebrated biological chemist, Professor at the College of France, member of the Institute and member of the Academy of Medicine. The deceased professor, who was born at Strasburg, commenced his career by being demonstrator of chemistry at the Conservatoire of Arts and Crafts. He was afterwards professor at the high school at Mulhouse, joint director of the laboratory at the Faculty of Sciences at Paris, and head of the chemical department at the College of France. M. Schützenberger has left behind him a number of important works bearing on the most diverse questions of organic chemistry. His admirable studies in fermentation are worthy to be the work of Pasteur himself. M. Berthelot, the permanent secretary of the Academy, reported its loss to the Academy in a speech recalling the services rendered to science by the deceased, who had been successively demonstrator to Dumas and Balard and who never ceased throughout his whole career to take an interest in the work of younger men.

The Monument to Duchenne of Boulogne.

On Sunday, June 27th, a monument was unveiled in the square of the General Infirmary of the Salpêtrière to the memory of the celebrated Duchenne, who was born at Boulogne in the year 1806, and is universally known by the title of Duchenne of Boulogne. M. Barthou, the Minister of the Interior, presided at the ceremony, and Professor Joffroy, physician to the Asylum of St. Anne and president of the memorial committee, pronounced an eulogium on Duchenne. He recalled the two great names of Trousseau and Charcot: of Trousseau, who made generally known the work of Duchenne with regard to locomotor ataxy, and of Charcot, who was, he said, the great worker in the science of modern neuro-pathology and one who had rendered the greatest possible service to the study of affections of the nervous system. On the pedestal of the monument is the following simple inscription: "1806–1875. To Duchenne of Boulogne. Localised electrisation; Physiology of movement; Neuro-pathology." Professor Raymond, physician to the Salpetriere, charged himself in his official capacity with the duty of demonstrating in their midst the innumerable labours of Duchenne. Dr. Lerboullet, of the Academy of Medicine, read a paper by Professor Mathias-Duval upon the works of Duchenne, and after an address by Dr. Motet, of the Academy of Medicine, who spoke in the name of the Medical Society of Paris, M. Barthou concluded the series of speeches. In the most brilliant fashion the Minister of the Interior tendered his respectful homage "to the marvellous unity and modesty of the great *savant* to whom they that day, perhaps somewhat tardily, were giving his well-deserved tribute of glory." A point to which the Minister did not refer at this official ceremony, at which the faculty and a host of medical office-holders were present, was that Duchenne never at any time was either a professor or a hospital physician. He worked all alone, going round the wards every morning examining and questioning the sick himself, and was looked upon as a madman by all the officials. Only by the worth of his works, and that at a long time after his death, has he attained his right position, for during his life he met with nothing but scorn from the official scientific world.

Congrès National d'Assistance at Rouen.

This congress has just finished its labours. M. Budin read a remarkable report upon infant feeding in crèches. According to him the chief cause of infantile mortality is diarrhœa brought on by bottle feeding such as has been in use during recent years. If cow's milk is sterilised this diarrhœa disappears. The milk should be given pure; it is useless and even dangerous to dilute it. Dilution increases the amount of fluid taken and the amount of urine passed by the infant, but stops growth. What is important is to avoid over-feeding. The amount of milk given with each bottle should be carefully limited and only increased very slowly, and in this way all digestive troubles will be avoided. Since the infants' department was instituted by M. Budin in June, 1892, at the Charity Hospital results have been obtained which exceeded his hopes. During these five years, even during the hottest weather, not one child has died from diarrhœa so long as they have been exclusively milk-fed, either on breast milk, or that of the cow sterilised, or a mixture of the two. The proceedings at the last sitting of the congress, presided over by M. Peyron, the head of the Assistance Publique, were most interesting. The first speaker took for the basis of his paper the system employed at Rouen, a system showing a remarkable progress. The organisation of the dispensaries had saved the hospitals great expenses, and by the establishment of dispensaries in various quarters of the town advice and treatment were brought to the very doors of the necessitous without their having to lose a day's work. M. Hendle, prefect of Rouen, continuing the debate, asked the congress to pass a resolution that home medical treatment should be developed on the largest possible scale and that dispensaries should be multiplied. Dr. Cerne argued that there should be some provision for rational treatment outside the hospitals, but not, he thought, at the patient's home. Experience showed that it was not necessary for every case, even though home treatment was impossible, to become an in-patient; it was quite sufficient to have an out-patient department of the hospital where treatment could be carried out and necessary operations performed. The surroundings would be better than those of the patient's home, and when he had been treated he could return there.

Dr. Boisleux and Dr. de la Jarrige.

Dr. Boisleux, who has recovered his health, has been transferred to the central prison at Melun. Dr. de la Jarrige remains at the Conciergerie, where he awaits the result of the appeal for a commutation of his sentence.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Bacteria in Yellow Fever.

DR. HAVELBURG, a German medical man residing at Rio de Janeiro, in Brazil, and well known by his researches on leprosy, has recently published in the *Berliner Klinische Wochenschrift* a communication on bacteria in yellow fever. Having found in necropsies of yellow fever patients great masses of a special micro-organism in the contents of the stomach, he endeavoured to isolate it in order to ascertain whether it was pathogenic or not. He found that from 1 to 2 c.c. of the contents of the stomach injected into the skin of guinea-pigs caused the death of the animals, and great masses of the above bacilli were discovered in the blood, while control experiments in which portions of the gastric contents obtained from patients who had died from other

Digitized by Google

diseases were injected into guinea-pigs had no fatal result. The alleged yellow fever bacillus is very small, its length being about 1 μ, = $\frac{1}{25000}$ of an inch, and its breadth from 0·3 μ to 0·5 μ. It is straight, and is for the most part isolated, the cohesion of two individuals being rather rare. The outlines of its extremities are especially well marked. It is easily stained by basic aniline colours, but not by Gram's method. It has not yet been ascertained whether it is motile or not. It can be grown on a gelatin plate, forming in twenty-four hours a white spot which in from twenty-four to forty-eight hours becomes larger and assumes the form of a pin's head. The gelatin is not liquefied. In a test tube the bacillus penetrates into the gelatin, giving the appearance of a white thread, and forms a thick white coating on the surface. On agar round white discs are developed, which may either remain isolated or may join together. Koch's bouillon is rendered opalescent by the bacillus in twenty-four hours, with formation of a grey, cloudy sediment. Broth containing sugar undergoes fermentation. In agar mixed with sugar a gas is produced which causes fissures in the agar. The bacillus coagulates milk within twelve hours; on potatoes its growth is rather slow; on blood serum it grows without any characteristic feature, producing opalescence and a sediment; on coagulated serum a pale grey film is formed.

Further Observations on the X Rays.

Professor Roentgen has again made a communication to the Royal Academy of Sciences on his great discovery. He states that while the x rays are passing through the air they traverse it in every direction. When a plate impervious to the rays is placed between a fluorescent screen and a source of the rays, so that the screen is overshadowed by the plate, the platinocyanide of barium nevertheless becomes luminous, and this luminosity is visible even when the screen lies directly upon the plate, so that one might imagine that some rays had traversed the plate; but if the screen placed on the plate is covered by a thick piece of glass the fluorescence becomes weaker and disappears completely when the glass is replaced by a cylinder of lead 0·1 cm (= $\frac{1}{25}$ of an inch) in thickness surrounding the fluorescent screen. Professor Roentgen's explanation of this phenomenon is that x rays emanate from the irradiated air. He considers that if our eyes were as sensible to the x rays as to ordinary light the appearance would be as if a candle were burning in a room filled with tobacco smoke. Professor Roentgen has, moreover, invented a new apparatus for measuring the intensity of the x rays. He has succeeded in ascertaining by means of this apparatus that the intensity of the rays is influenced: (1) by the course of the primary current; (2) by the interposition of a Tesla transformer; (3) by the rarefaction of the air in the tube; and (4) by some other agencies not yet known. He concludes (1) that the rays issuing from a discharging apparatus consist of a mixture of rays of different absorbability and intensity; (2) that the combination principally depends on the course of the discharging current; (3) that the absorption of the rays varies according to the absorbing medium; and (4) that as the x rays are produced by the kathode rays, and have similar fluorescent, photographic, and electrical qualities, it is very probable that they are both phenomena of the same nature.

The late Pastor Kneipp.

Pastor Kneipp, the founder of the therapeutical system called the Kneipp cure, died last week at Wörishofen, in Bavaria. He must not be confounded with the ordinary quacks—unfortunately so numerous in this country—firstly, because he took no fees for his attendance, but was recompensed only by donations given by his patients to charities under his patronage; and, secondly, because many persons really derived some benefit from his advice. His injunctions of plain diet, cold bathing, walking barefooted on wet grass, and early going to bed and early rising were undoubtedly useful to patients with nervous troubles brought on by an injudicious way of life; but as he paid little attention to diagnosis his treatment often did harm to patients with organic diseases, whom he caused to live like the robust peasants of the Bavarian mountains. Nevertheless, the number of people coming from every part of the world increased from year to year, so that the little village of Wörishofen in course of time was changed into a modern health resort, provided with large and comfortable hotels. With the money he received Pastor Kneipp founded asylums, infirmaries, and other benevolent institutions, which, however, according to an inquiry conducted by the Munich Medical Society, did not by any means fulfil the requirements of modern hygiene. He never left his village except when he was once summoned to attend the Pope and on the very rare occasions when he visited some of the cities of Germany for the purpose of addressing public meetings and propagating his views. His theoretical knowledge of medicine being far beneath that of a first year's medical student, the speeches which he delivered at these meetings were a source of amusement to the medical men who happened to be present; but, strange to say, many sanatoria have, nevertheless, been formed throughout Germany by medical men and others where his treatment is fully carried out. His personal character was recognised as blameless even by his adversaries. Although raised to the high rank of a prelate of the Church of Rome, he continued to live as an ordinary country clergyman, and died without having made any personal pecuniary profit out of the great popularity he enjoyed.

June 28th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Bacillus Icteroides.

THE LANCET has already told its readers the circumstances under which Dr. Giuseppe Sanarelli, sometime *privat-docent* at the University of Siena, now Professor of Hygiene in the Medical School of Montevideo, set himself to discover the bacillus of yellow fever;[1] how he conducted his observations, clinical and bacteriological, at the Lazzeretto of the Island of Flores and at the hospital of S. Sebastiano at Rio Janeiro; and how, after having himself contracted the fever and fortunately recovered, he continued his researches until, in the later months of last year, he satisfied himself that he had found the bacillus, and embodied his conclusions and the investigations that led up to them in a monograph which he deposited with the Accademia Medica di Roma. Thereafter, having by fresh studies checked his previous ones and confirmed his conclusions, he thought fit to give the result to the profession and the world. This he did lately before a scientific audience at Montevideo, and the substance of his lecture, first announced in the lay press by telegraph, I can now supplement by minuter details. It was at the Lazzeretto on the Island of Flores that he first came upon the "microbe of yellow fever." At the outset he had difficulty in distinguishing among a varying number of microbes the unvarying one of which he was in quest; but at last he found it—never, indeed, unaccompanied by others, but always preserving its characteristic features, while its occasional companions were protean. Contrary to expectation, it was not in the alimentary canal that he came upon it. Never, indeed, has he detected it there; but in the circulation and in the tissues he found it invariably, and so was able to correct the current belief that the poison of yellow fever resides in the intestinal tract, showing, on the contrary, that it is formed in the *vie intime* of the tissues and in the circulation itself. Morphologically, the microbe, to which he has given the name of "Bacillus Icteroides" presents at first sight little or nothing characteristic. Closer investigation identifies it as a very small "baston-cino" (rod) with rounded extremities, generally combined in pairs in the cultures and in little groups in the tissues; in length from two to four thousandths of a millimetre, and for the most part twice or thrice as long as it is broad. It is pathogenic for the majority of the domestic animals—a conclusion arrived at by Professor Sanarelli after experiments made on 2000 of these. Few microbes, indeed, have a wider diffusion, every mammal on which he experimented having shown itself more or less sensitive to its pathogenic action, while the feathered tribe, on the other hand, were quite irresponsive. White rats it kills in five days, the infection gaining a foothold through every channel, including that of respiration. Once admitted into the organism the microbes collect in greatest force in the spleen, where they remain during the whole evolution of the malady without noteworthy multiplication. After from six to seven days they all at once pass into the circulation, enter on a period of proliferation, and kill by septicæmia. The rabbit is highly sensitive to this pathogenic action, dying in from four to five days if the poison has entered by the subcutaneous tissue, and in

[1] THE LANCET, Jan. 9th and April 3rd, 1897.

Digitized by Google

two days if it has been injected into the blood. In the dog are obtained results showing the fever to be "an infective malady due to a micro-organism well defined and susceptible of being cultivated by means of the ordinary artificial nutrients." The bacillus, moreover, may be isolated, not only from the corpse, but even during the life of the patient. Once isolated, its bacteriological diagnosis can be completed in twenty-four hours, possessing as it does characters so distinct as to make it readily recognisable among all the microbes hitherto brought to light. The scanty number in which it is found in the organism and the violence of the symptoms point to its action as that of a very energetic poison. The dog, as already stated, illustrates this action most significantly—scarcely less so the goat, the ass, and the horse; while the cat is curiously refractory. The fever which he claims to have reproduced in man has not a few points in common with typhoid fever, and he emphasises the fact that the diffusion of the virus may be effected through the air as well as by water, contagion being possible through the respiratory system. The bacillus favours the entrance into the organism of septic microbes while its own action on the liver is peculiarly energetic, inducing rapid atheromatous degeneration with other anatomical lesions, to which is due, in some measure, the icterus characteristic of the disease. The liver loses all functional activity. Performing a conservative *rôle* against the poisons and microbes which would otherwise attack the organism from the intestines, that *rôle* fails when these microbes overcome its resisting power. They thus conquer and eliminate from the organism the bacillus icteroides, and in this way Dr. Sanarelli explains those cases in which the bacillus is no longer found on post-mortem examination, or, if found at all, found only in a medley of other species of microbes.

The bacillus acts on the kidney by inducing inflammation of peculiar intensity. This is followed by lesions evinced by the albuminuria characteristic of the last period of the yellow fever; then anuria supervenes, the result of a "true and idiopathic uræmia." Thus it happens that patients when they do not directly succumb to the poison and the lesions caused by the "bacillus icteroides" may die by the secondary infection or by uræmia.

The *modus operandi* of the bacillus having thus been demonstrated Dr. Sanarelli next investigates its mode of entering the organism. As already stated, he denies that its "sede elettiva" (elective seat) is the alimentary canal. He is even inclined to doubt (what elsewhere he provisionally granted) that it may find admission through the water. Atmospheric transmission is the channel he favours. While denying that the alimentary canal is the "elective seat" of the malady, he is far from ignoring the possibility of its being a mode of entrance for the bacillus. "The catarrhal processes of the liver," he maintains, "to which new-comers in tropical regions are subject, and the apparently trifling disturbance of the digestive tract may in this case facilitate the passage of the bacillus into the organism. At this point he enlarges on another "fenomeno biologico," which illustrates the action of the bacillus and the genesis of yellow fever on board-ship. Badly-aired vessels are impregnated with a "fetida umidità" which, with heat and the want of ventilation, forms the "coefficient of epidemics developed at sea." This atmosphere, on experiment, proved particularly favourable to the energising effect of the bacillus icteroides. In certain cultures, continues Dr. Sanarelli, when this micro-organism, sown for some time, seemed not to have "caught on," the "muffa" (or air mildew) sufficed to develop the "colonie caratteristiche" of the bacillus of yellow fever, and it is probable that on board-ship the preservation and "pullulazione" (germination) of the bacillus are due less to moist heat considered as a physical agent than to the generation of "muffe" favoured by the condition of temperature and humidity prevalent in ships at sea. On the other hand (Dr. Sanarelli proceeds), the notable resistance the bacillus icteroides offers to the principal factor of natural disinfection, desiccation, to wit, and the great longevity it achieves during voyages, sufficiently explain the ready acclimatisation of yellow fever and its stubborn persistence on seaboards which have been visited by it.

On the prophylactic and therapeutic aspects of yellow fever Dr. Sanarelli promises special work. In the latter field he has, I believe, a serum in contemplation from which he anticipates results not less satisfactory than those yielded in diphtheria. Meanwhile, we may echo the congratulations voiced by his compatriot, Dr. Alberto Guidi (whose notes from Dr. Sanarelli's monograph I have freely made use of), and record our admiration for the thoroughness, the patience, and the courage with which the young Sienese physician has "broken ground" in a difficult and dangerous field.

June 26th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Pilgrims and Quarantine.

THE Quarantine Board at Alexandria has had plenty to occupy it during this month. The discovery of typhus fever among several flocks of recently imported sheep necessitated the destruction of many hundreds in the quarantine parks. If it is true that typhus fever or rinderpest can be introduced into Egypt as easily by sheep as by cattle it is a pity that stringent measures are not adopted to prevent the importation of all sheep from infected ports. In 1884 regulations of this kind were made in Egypt for cattle, and it is noteworthy that bovine typhus fever has never appeared in this country since that date, the last epidemic having been in 1883. But veterinary diseases are as nothing compared to human cholera and plague. The Board, after several meetings and much anxious deliberation, decided not to interfere with this year's pilgrimage in spite of the presence of cholera bacilli at El Tor. This decision was apparently based on the idea that when clinical symptoms do not coincide with the bacteriological diagnosis the latter is to be entirely disregarded. This is a dangerous precedent and somewhat subversive of the modern system of allowing bacteriologists to have a casting vote in cases of doubt. Imagine a man with a cough, but all other symptoms and signs of doubtful obscurity. If tubercle bacilli are found in his sputa the case would surely be treated for the time being as one of tubercle. It does not seem irrational to expect that a man with diarrhœa and cholera bacilli in his dejecta should be considered—temporarily at least—as suffering from cholera. But the Board decided otherwise, and the Bosnian and Herzegovinian pilgrims in question passed on to Turkey unmolested. The Egyptian Government, in spite of the absence of suspicious cases among Egyptian pilgrims, noted the names and addresses of all returning pilgrims, and had them visited for five days by the medical man of their own district. Hardly had the cholera scare died away than some cases of plague were reported at Jeddah, and this time the Board promptly settled that the pilgrimage must be declared "unclean." It is unknown how the plague reached Jeddah, but one of the obvious possibilities is that it was brought there from Assir, the plateau between Hedjaz and the Yemen, where plague is said to be always endemic. The existence of this district is an additional reason for starting some bacteriological work in Jeddah or Mecca. A Mussulman might be sent there this autumn to begin preliminary investigations. In the meantime Egypt is free from cholera and plague and in many ways prepared to receive these unwelcome visitors if necessary.

Infectious Diseases.

During the last six weeks three specific fevers have been reported from the provinces. Small-pox has broken out in most of the Lower Egypt provinces and half those of Upper Egypt; 795 cases have been reported and 183 deaths. Typhus fever, including probably a few cases of relapsing fever, has occurred in ten places, causing 35 deaths out of a total of 195 cases. Measles has been present in five provinces, accounting for the high death-rate of 122 out of 178 cases. It must be remembered that the native doctors' diagnosis is often made after death, and should always be received with suspicion.

Cairo, June 20th, 1896.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Deaths of Dr. J. Lewis Smith and Dr. Wm. Lusk.

DURING the last week the medical profession of this city and country has lost by death two of its most prominent members. Dr. J. Lewis Smith died on June 9th at the

Digitized by Google

ripe age of seventy years. His health had been impaired for several years, but he still continued the active duties of his profession until within a day or two of his death. Dr. Smith adopted the diseases of children as a specialty at the commencement of his professional career in 1853, and was the pioneer in this department of medicine in the United States. His first contribution to the literature of this subject appeared in 1854, and from that date to his death he was a prolific contributor to the current medical periodicals, the total number of his papers exceeding one hundred and fifty in number. His work on "The Diseases of Children" appeared in 1869 and passed through eight editions, the last of which was recently issued under his personal revision. For a quarter of a century this work has maintained its position as the accepted text-book of the schools and the favourite authority of the profession. Dr. Smith was for twenty years Clinical Professor of Diseases of Children in Bellevue Medical College. Dr. Lusk died suddenly on June 13th from an apoplectic attack at the age of sixty years. He was dean of the Bellevue Medical College and Professor of Midwifery in that institution. His reputation in the department of obstetrics rests on his treatise on midwifery, which took the highest rank on the issue of the first edition. It has been translated into several languages.

Medical Schools fail to Consolidate.

The attempt to consolidate the University Medical College and the Bellevue Medical College has not succeeded. The trouble seems to have arisen when the scheme reached the point of making up a faculty out of the existing faculties. The friends of the schools are greatly disappointed at the result, for they anticipated the creation of the best equipped medical school in the United States.

Food Adulteration in the United States.

According to Dr. Fremkel the extent to which food adulteration is carried in the United States is a matter of doubt. The estimates of competent authorities on the subject vary between from 2 to 15 per cent. There is no question that the first figure is too low. The last is given by the special agent of the Department of Agriculture, who has examined the subject very exhaustively. Good judges estimate the value of the food supply of the United States at a minimum of $4,500,000,000 annually. If we take the very onservative estimate of 2 per cent. the loss to the consumer by adulteration amounts to $90,000,000 per year. Dr. McNeal, of Ohio, estimates the annual loss to the people of the United States at one and one-third billion dollars; and to the state of Ohio as the result of three years' investigation, a loss of $78,000,000 annually, or $232,000 per day.

The Treatment in a Case Decided to be "Hearsay Evidence."

In a recent case where it was desired to prove that the plaintiff suffered a severe injury to the spine the attempt was made to prove that fact, not by the testimony of the physician who had attended her, but from the treatment that she had received. Such proof, the appellate division of the Supreme Court of New York think, was in the nature of "hearsay." The treatment of the plaintiff for a particular disease, it maintains, was no more than a declaration of the physician that she was suffering from such a disease; and as the declaration would not be competent the court holds that the proof of the treatment was not competent.

The Anti-vivisection Bill in the United States Senate.

Senator Gallinger has reported the Bill to regulate vivisection in the district of Columbia. He accompanies the Bill with a very full report which discusses the subject for and against the Bill from the evidence presented to the committee. He appends a most impressive list of names of some of the most influential people in the country who favour and urge the passage of the Bill. It is very plain that the efforts of the vivisectionists to defeat the Bill have attracted unusual attention to this measure, thus arousing a large opposition from very prominent persons who evidently do not clearly understand the situation, but whose expressed wish and great numbers have influenced the Senate committee. The Bill provides—(1) for the use of anæsthetics in all painful experiments on living vertebrate animals, the so-called inoculation experiments, test of drugs and medicines and cases of recovery from surgical procedure being expressly exempted from this requirement; (2) for the licensing of all experimenters by the district commissioners, except those who are duly authorised officers of the Government of the United States or of that of the district of Columbia; (3) for the prohibition of vivisection in the public schools and in exhibitions for the general public; and (4) for the inspection of all places of experiment by inspectors to be appointed by the President of the United States.

Prosecution of Quacks.

It appears that since April, 1895, when the law providing for the criminal prosecution of quacks was restored, the New York County Medical Society has caused the arrest of eighty-three persons for practising illegally, and it has obtained convictions in fifty-one cases. These persons have paid $3690 in fines, and a number of them have been sent to gaol besides. The legal department of the society has a large number of cases pending. This fact alone is deterrent of much illegal practice, and not only tends to prevent the pretenders from trying to establish themselves in New York City, but also drives some of them to other localities where the duty of prosecuting offenders is not undertaken by the profession.

The Hospital Fund of New York.

The Hospital Saturday and Sunday Association, the receipts of which for this year amounted to $61,500, have distributed of this sum $50,000 among 35 institutions. The sum of $8200 was designated for special purposes and $3300 was reserved for expenses. The collections were $2500 more than last year, and the number of "free hospital days" was 690,841.

June 16th.

MONTREAL.

(FROM OUR OWN CORRESPONDENT.)

Victorian Order of Nurses.

EVERYTHING just now is tinctured with Jubilee, from politics to postage stamps. The chief scheme for a Canadian Colonial commemoration is that of the Victorian Order of Nurses. This ambitious but somewhat visionary project is greatly exercising the colonial mind, both lay and medical. The main feature of the project is to dot the cities in the Dominion with "training centres," and the sparsely populated parts with "residential centres," in which a supply of trained nurses would be housed, to be in readiness to go to sick calls where skilled nursing is not now available; the remuneration of the nurses to be from an endowment, the friends of the sick to pay what they are able. The project is receiving the backing of our highest social circles, and it will need it all to make it go. From a pamphlet dealing with the duty and charm of nursing the sick, issued under the ægis of Lord and Lady Aberdeen, I take the following: "Some of the chief objects of the order will be: To provide skilled nurses in sparsely settled and outlying country districts; to provide skilled nurses to attend the sick poor in their own homes in cities; to provide skilled nurses to attend cases in cities at fixed charges for persons of small incomes, the charges being paid to the funds of the order; to provide small lying-in rooms and wards in cottage hospitals or homes; to prepare trained nurses thoroughly qualified to carry out these objects. It would not be a prudent thing to have the order started unless provision be made for perpetuating it. It would take an endowment of about £200,000 to insure revenue to make this benefaction a lasting one for all the needy districts of Canada. Shall we confess ourselves helpless in the presence of this urgent need and dismiss the cry for help with the remark, 'But a million of dollars is a great sum to raise'? Certainly a million of dollars is a great sum to raise, but if the people of Canada can be fully informed and thereby awakened to the greatness and goodness of this movement, a million dollars will be forthcoming for the commemoration of the Diamond Jubilee of Her Majesty by such means as will cause gratitude to grow continually in the hearts of the people of Canada towards the memory of Victoria the Good and her representatives and subjects in Canada who promoted the order." The following paragraph from the pamphlet has given offence to some sensitive ones in the medical profession: "In the sparsely settled parts of Canada what is needed now more than ever before is the presence in scores of localities of skilled physicians who have forgotten the meaning of personal ease—men who believe that the nobility of living is to help others

Digitized by Google

and not to roll up riches. These country sections call for competent medical men; and if the medical men are supplemented by trained nurses they could each cover more ground. The trained nurses would also carry valuable knowledge of a most practical sort into the homes of the people." At first there was a chorus of praise of the scheme from the leaders of the medical profession, but now murmurs of dissatisfaction are heard. Two provincial medical bodies have given public expression of disapproval of the scheme. One association in annual session felt moved to express its "most unqualified disapproval ..... on account of its dangers to the public."

A Millionaire's Will.

The body of the late Mr. J. H. R. Molson, the millionaire banker and brewer, who died last week, was taken to Boston, U.S., for cremation. Mr. Molson was one of the members of a family whose name is indissolubly connected with the McGill University by reason of frequent and vast benefactions. Among the many of Mr. J. H. R. Molson's contributions were the land on which is erected the Redpath Library and £15,000 for the extended buildings of the medical faculty. Mr. Molson's will contains a bequest to the McGill University of £20,000 as an endowment for general purposes; £2000 for the Montreal General Hospital; £2000 for a crematorium to be erected in Mount Royal Cemetery, the bulk of the vast fortune going to relatives, there being no direct heirs.

Montreal Meeting of the British Medical Association.

In my last communication reference was made to the work of the Museum Committee of the British Medical Association, and among other things I stated that some disappointment had been felt on account of the comparatively few applications for space by exhibitors up to that time. It appears now that the tables have been much sought after, and in consequence the exhibitors will be more numerous than was originally anticipated by the committee. It is further expected that the successful work of this committee will result in augmenting the funds of the executive by some £300 or £400. Altogether the Montreal meeting promises to be in every respect a success.

Provoked Gangrene.

Two interesting cases were shown recently at the Medico-Chirurgical Society in which this diagnosis was reached. Both were young women; in one case there was on the lower third of the calf a round sore with a black crust the size of a silver dollar. The patient stated that she had had typhoid fever, and also that she had had a similar sore once before. The sore was a long time in healing, but ultimately the patient went out well. The hospital physicians, though not unanimous, were mostly of the opinion that the case was as stated. The patient had acted rather queerly, and on one occasion succeeded in setting fire to her clothing. The agent used was thought to be carbolic acid, and the reason of the slowness in healing was the constant irritation of the part by the patient. The other case was that of a hysterical young girl who had destroyed the little finger of the left hand, also by carbolic acid.

An Easy Diagnosis.

The liberty of the individual is well safeguarded in the province of Quebec, so that when one wants to get a patient in an asylum much formality is required. Lengthy papers have to be signed by two practising physicians who have made independent visits to the patient. One of our asylum officers recently stated in a discussion that he was once requested to accept a man as an inmate on a document in which the attending physician gave as the only basis of his diagnosis of dangerous lunacy the following: "He tells lies."

A Medical Association's Jubilee.

The meeting of the American Medical Association of Philadelphia held from June 1st to June 5th was a notable one, being its fiftieth. The attendance was very large. The oratorical and scientific parts were excellent, and the hospitality was lavish. The serum typhoid test was discussed at length at one of its sessions. Wyatt Johnston, of Montreal, supported his dried blood method by enlarged experience. There is a tendency now to consider the agglutination as a symptom rather than a test of typhoid fever. The normal blood of negroes frequently agglutinates.

June 12th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Hospital for Phthisical Patients, New South Wales.

LADY HAMPDEN has proposed that the record reign of Queen Victoria should be commemorated in New South Wales by the establishment of homes or hospitals for phthisical patients, and at a meeting held at Government House it was decided to carry this proposal into effect. As has been pointed out in previous communications, the need for such institutions is beyond question, and their establishment now would be a very excellent permanent memorial of the Queen's reign, and one in accord with her own wishes.

Inadequacy of Quarantine Arrangements at Port Phillip.

The resources of the quarantine station at Port Phillip Heads have been somewhat taxed recently, as two mail steamers, the *Nineveh* and the *Himalayeh*, have come into port with small-pox on board and the Melbourne passengers have been quarantined. As usual, they have grumbled, said the case alleged to be small-pox was not small-pox, and that the arrangements for their reception at the station were inadequate. Dr. Gresswell, the chairman of the Board of Health, admits that the equipment of the quarantine station is not all that is desirable, but that the arrangements must be always of a more or less temporary character, and all the convenience of a first-class hotel cannot be expected. The mail steamer *Polynesian* arrived at Adelaide with two alleged cases of small-pox on board, and was quarantined there pending investigation. The cases, however, proved to be chicken-pox.

Outbreak of Dengue Fever.

An epidemic of dengue fever has occurred at Normanton, Queensland, to such an extent that nearly every inhabitant has been affected. The warders in the gaol succumbed to the disease, and the prisoners have been released and the gaol turned into a temporary hospital. Those who had been long resident in the district enjoyed immunity for a time, but at last were affected like the others.

The Diet of Australians.

Mr. P. Muskett, in the first of a series of lectures at the School of Arts, Sydney, on the "Alimentary Properties of Vegetables," said that an Australian annually would eat as much meat as two Englishmen, three Canadians, four Germans, and ten Italians, and that the health of Australians was suffering in consequence. Indigestion was the Australian national malady. He advocated a much more extended use of vegetables. Excessive tea-drinking was another cause of much ill-health among Australians.

New South Wales Medical Union.

The fourth annual meeting of the New South Wales Medical Union showed that this society was in a flourishing and vigorous condition. Its members' roll had steadily increased and it had a good balance in the bank. In several instances during the year members had been threatened with legal proceedings, but on the council intimating its intention to defend the cases the proceedings were dropped. The council had taken legal advice as to whether any form of indemnity given to a medical practitioner was binding in law, and the opinion obtained was that all such agreements are void in law. The following resolution was carried unanimously at the meeting: "Where any society, syndicate, or organisation exists having amongst its objects the affording of medical aid to its members or to the public, or both to its members and the public, and the council shall by resolution have decided that such society, syndicate, or organisation is prejudicial to the interests of the medical profession, no person pecuniarily interested in, or otherwise connected with, such society shall be eligible for membership of the union, and if such a person be a member he may be expelled. No person who practises as a homœopath shall be eligible as a member."

St. John Ambulance Association.

The annual demonstration of the Victoria Centre of the St. John Ambulance Association was held recently in the Town-hall, Melbourne. The President, Sir William Clarke, Bart., was in the chair, and His Excellency the Governor addressed the meeting. The work of the association had steadily progressed and it had now about 10,000 members, more than half of whom were qualified to render first aid.

Digitized by Google

Litters were now available in all cases of emergency. The number of pupils for the year was 747, of whom 497 passed the examination.

Death of William Gardner, M.D., C.M. Glasg.

By the death of Dr. William Gardner Australia has lost one of her most notable surgeons. A bold and dexterous operator, he also contributed largely to surgical literature, and was especially identified with the subject of the surgical treatment of hydatid disease. He originated the operation of neurectomy of the posterior divisions of the spinal nerves for spasmodic torticollis. His operation for this affection was very similar to that devised by Mr. W. Keen, but was quite an independent suggestion, and, indeed, really somewhat prior in point of time. Dr. Gardner was also a pioneer in renal surgery in Australia, and was the first to perform Loreta's operation and excision of the larynx in these colonies. In 1892 he was President of the Section of Surgery at the Inter-colonial Medical Congress of Australasia, and delivered an admirable address, which received especially favourable commendation from the members who heard it. He, in 1894, founded the *Inter-colonial Quarterly Journal of Medicine and Surgery*, which was subsequently amalgamated with the *Australian Medical Journal*. Dr. Gardner made his reputation in Adelaide, where he had a very large practice, and was for many years senior surgeon to the hospital and lecturer on surgery at the university. In 1892 he removed to Melbourne, and in 1895 his health began to fail. In 1896 he took a holiday in Europe, but died at Naples on his return voyage to Australia Dr. Gardner was a man of intense energy and great decision of character, and was also sympathetic with his patients, who trusted him implicitly. No doubt, like many another man of strenuous temper, he had many controversies and made not a few enemies, but he worked hard with no ambition other than the advancement of his profession, for which he had a consuming enthusiasm.

Operating Theatre at Prince Alfred Hospital, Sydney.

The operating theatre at the Prince Alfred Hospital, Sydney, has been considerably enlarged and altered so as to bring it into conformity with the very latest aseptic ideals. The floor is of Belgian tiles, and the walls have a dado of marble. Sterilised water is laid and the furniture is of glass and iron of the most modern and approved pattern. The lighting and ventilation have received special attention, and also the arrangement of the seats for students, and it is claimed that the theatre is now the most perfect in Australia.

Thyroid Gland Extract as a Galactagogue.

The *Inter-colonial Medical Journal* for April contains a paper by Dr. R. R. Stawell on Thyroid Gland Extract as a Galactagogue. He publishes notes of cases where he administered this substance for the purpose of increasing the metabolism in the mammary gland. On the assumption that thyroid extract increased metabolism generally, and as the secretion of milk is typical of metabolism, it was reasonable to suppose thyroid would act as a galactagogue. Nine cases are given in which it was tried, and Dr. Stawell says: "While very fully alive to the danger of making generalisations based on only a few clinical observations, it seems to me that there is sufficient evidence that thyroid extract is an apparent galactagogue in certain cases."

Epidemic of Infantile Paralysis.

In the *Australasian Medical Gazette* for April Dr. C. A. Altmann describes a series of fourteen cases of acute anterior polio-myelitis which occurred in the district of Port Lincoln, South Australia, during the months of March and April, 1895. The last case before the series was an isolated one in 1887, and no cases have occurred since. The proportion of cases to population amounted to 1 in 108. In two instances two members of the same family were attacked in rapid succession. All the patients but one were over three years of age; eight were males and six females. The season was hot and dry, and excessive exertion seemed to be a predisposing cause in one case. One patient had retention of urine, one had hemiplegia, and one had paralysis of the seventh nerve.

Case of Acromegaly.

At the April meeting of the Medical Society of Victoria Dr. J. W. Barrett exhibited a well-marked and typical case of acromegaly. The patient had optic atrophy, hemianopsia, and proptosis, obvious enlargement of the hands and great toe, and a suggestion of kyphosis. A skiagram of the hands of the patient showed marked enlargement of the middle of the phalanges.

May 12th.

Obituary.

SURGEON-GENERAL HERBERT TAYLOR READE, C.B., V.C.

HERBERT TAYLOR READE, who, in addition to the much coveted distinction of the Victoria Cross, also held the post of Honorary Surgeon to the Queen, died at his residence, Park Gardens, Bath, on Wednesday, June 23rd, 1897. The deceased officer was born in 1828 and qualified as M.R.C.S. Eng., in 1849. The following year he joined Her Majesty's Service as an army surgeon and was appointed to the 61st Regiment. With this regiment he was present at the siege and capture of Delhi from July to September, 1857. The following is the official account of the act for which he received his Victoria Cross:—"During the siege of Delhi on Sept. 14th, 1857, while Surgeon Reade was attending to the wounded at the end of one of the streets of the city, a party of rebels advanced from the direction of the Bank, and having established themselves in the houses in the street, commenced firing from the roofs. The wounded were thus in very great danger, and would have fallen into the hands of the enemy had not Surgeon Reade, drawing his sword and calling upon a few soldiers who were near to follow, succeeded under a very heavy fire in dislodging the rebels from their position. Surgeon Reade's party consisted of about ten in all, of whom two were killed and five or six wounded. Surgeon Reade also accompanied the regiment at the assault of Delhi, and on the morning of Sept. 16th, 1857, was one of the first up at the breach in the Magazine, which was stormed by the 61st Regiment and the Belooch Battalion, upon which occasion he, with a sergeant of the 61st Regiment, spiked one of the enemy's guns." In 1856-1857 Surgeon-General Reade was principal medical officer of the Southern District. At the end of 1857 he retired from active work, and in 1895 was made an honorary surgeon to the Queen.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men have been announced:—Dr. Stocquart, Chief Demonstrator in the Anatomical Department of the University of Brussels.—Dr. Dominik Hofer, for many years Professor of Anatomy in the Munich Veterinary School. He was eighty-nine years of age and qualified as a medical man in 1845.—Dr. Martin Wilckens, who had formerly been in practice as a medical man in Hamburg, but who for many years had occupied the chair of Animal Physiology in Vienna, has shot himself in consequence it is said, of increasing paralysis which was due to calcification of the arteries.—Dr. Giuseppe Fissore, Extraordinary Professor of Medical Pathology in Turin.—Dr. Thomaz de Carvalho, Emeritus Professor of Surgery in Lisbon.—Dr. Cernea, Professor of Internal Pathology in the Jassy School of Medicine.

"QUEEN'S DAY" AT THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The President of the hospital, the Duke of Westminster, has fixed Saturday, July 10th, for "Queen's Day," and the Duchess of Albany and Duchess of York have promised, if possible, to be present. In the afternoon there will be an inspection of the wards and a musical conversazione, and in the evening a "Dream of Flowers."

THE RAINY SEASON IN INDIA.—The forecast issued by the Indian Meteorological Department relative to the monsoon has prognosticated that the rains would probably commence on the Bombay coast about the second week and on the Bengal coast about the third week of June. The *Times of India* says that the heat at present prevailing in various parts of India is abnormally great, and the rains will be greatly welcomed. Looking to the late famine, arising from the failure of crops, a good monsoon is of the greatest importance to the country. Severe thunderstorms, attended with heavy falls of rain, have occurred at various places in India.

Medical News.

CAMBRIDGE UNIVERSITY.—At the examinations for medical and surgical degrees, Easter term, the following candidates were successful in the subjects indicated:—

FIRST EXAMINATION.

Part I.

Chemistry and Physics.—Birks, King's; Brailey, Downing; Buckle, Conville and Caius; Burroughes, Trinity; Cardew, Clare; F. J. Child, B.A., Christ's; Cooper, Jesus; Crowfoot, Emmanuel; Crowther, St. John's; Cunnington, non-collegiate; Daly, St. John's; Day, Gonville and Caius; Day, Christ's; Dodd and Donnell, Gonville and Caius; Elliott, Emmanuel; W. I. Evans, St. John's; Freshwater, Trinity; Goss, Jesus; C. H. Gregory, Emmanuel; Gubbins, Clare; Guthrie, King's; P. Hardy, Trinity Hall; Harnett, St. John's; Harrison, Clare; Heald, non-collegiate; Hepburn and W. H. Hills, Pembroke; Hocken and Hudson, Clare; Kidd and Lidward, Trinity; Leech and Lucas, Clare; H. B. McCaskie, Gonville and Caius; C. G. Martin, Downing; Mathias, Trinity; Nicholson, King's; Panton, Trinity; Pellier, B.A., Clare; Pellow, St. John's; Pennington, B.A., Gonville and Caius; Pipkin, Emmanuel; Pope, Trinity; Rickett, King's; Riddle, Peterhouse; Robbins, Trinity; C. T. Y Robson, M.A., St. John's; Rolfe, Clare; Scott, Sidney-Sussex; Sidgwick, Clare; Simpson, King's; W. H. E. Stewart, Gonville and Caius; Strong, B.A., and H. C. Taylor, Trinity; Thurlow, Gonville and Caius; Tuck, Emmanuel; Watson, Gonville and Caius; Ward, Clare; Williams, B.A., Pembroke; Wollaston, B.A., King's; Young, Christ's; and Young, Emmanuel.

Part II.

Elementary Biology.—H. Akroyd, Gonville and Caius; Armitage, Emmanuel; Bain, Trinity; Barton, Pembroke; Birks, King's; Brailey, Downing; Breakey, Jesus; Burroughes, Trinity; Cardew, Clare; Clapham and Cohen, Emmanuel; Cooper, Jesus; Cooper, Emmanuel; Courthauld, Trinity; W. R Creighton, Emmanel; W. L. Cripps, Trinity; Crowther, St. John's; Cunnington, non-collegiate; Davidson, Gonville and Caius; Day, Christ's; Dodd, Gonville and Caius; T. R Elliott, Trinity; Elliott, Emmanuel; W. I. Evans, St. John's; Frere, Pembroke; Gardner, Gonville and Caius; Gardner-Medwin, Trinity; Goss, Jesus; Goulden, non-collegiate; Goyder, St. John's; C. H. Gregory, Emmanuel; Gubbins, Clare; Guinness, Emmanuel; Guthrie, King's; Haldane, Jesus; Hardwich, Trinity; Hardwick-Smith and Harnett, St. John's; Harrison, Clare; Harry, Jesus; A. G. Harvey, St. John's; Haynes, Downing; Hocken, Clare; Holtzman, Christ's; Iles, Gonville and Caius; E. G. Kellgren and Kidd, Trinity; Kirk, King's; Ledward, Trinity; Leveaux, St. John's; H. B. McCaskie, Gonville and Caius; J. C. Matthews, Downing; Morris, Gonville and Caius; R. C. Mott, Trinity; Murphy, St. John's; Muspratt, Christ's; Nicholson, King's; Norman and Paramore, St. John's; Parry, Gonville and Caius; Pellier, B.A., Clare; Phelps, Trinity; G. L. Ranking, Pembroke; Rickett, King's; Robbins, Trinity; C. T. Y. Robson M.A., St. John's; Rolfe, Clare; Salzmann, Pembroke; Scarborough, St. John's; Scott, Sidney-Sussex; Sidgwick, Clare; Simpson, King's; Snell, Gonville and Caius; Strong, B.A., and H. C. Taylor, Trinity; Thurlow, Gonville and Caius; Tonge and Tuck, Emmanuel; Ward, Clare; B. B. Watson, Trinity; L. G. A. West, St. John's; Whitaker and L. E. Wigram, Trinity; H. M. Wilson, Trinity Hall; Wiltshire, St. John's; Woolley, King's; and E A. Wright, H. Selwyn.

SECOND EXAMINATION.

Part I.

Pharmaceutical Chemistry.—J. F. Alexander, Trinity; Beck, Clare, S. Bennett, Downing; Bennion, St. John's; H. C. Brown, Emmanuel; Bulstrode, Trinity; Bryan and Byles, King's; Candler, B.A., Corpus Christi; E. R. Clarke, St. John's; Cole, Trinity; de Havilland, M.A., Peterhouse; W. H. Dickinson, B.A., Trinity; Edwards, Downing; Etherington-Smith, Trinity; H. R. Fisher and W. H. Fisher, Emmanuel; W. S. Fox, Trinity; Heath, Downing; H. T. James, B.A., Trinity; Jeudwine, H. Selwyn; J. H. Kellgren, Trinity; Lambert, St. John's; McBryde, B.A., King's; Mart, St. John's; H. W. Masterman, Christ's; C. M. Murray, Pembroke; S. H. Natban, Inc., and Noon, Trinity; Payne, Peterhouse; Rischbieth, Rix, Robinson, and E. A. Ross, Trinity; Sapwell, B.A., Corpus Christi; A. V. Sedgwick, Gonville and Caius; Shone, Emmanuel; Spicer, Trinity; Stiebel, Trinity Hall; Stocker, Trinity; Trigg, Christ's; Wales, Sidney-Sussex; Wild, Jesus; and Wilson, H. Selwyn.

Part II.

Human Anatomy and Physiology.—A. P. M. Anderson, B.A., Trinity; Barnicot, B.A., Pembroke; Brenan, B.A., Trinity; Candler, B.A., Corpus Christi; E. R. Clarke, St. John's; Cooke, B.A., Sidney-Sussex; Dunne, Queen's; Eve, B.A., Emmanuel; Gillespie, St. John's; Glenn, B.A., Pembroke; Glover, St John's; D. C. Hall, Emmanuel; Heath, Downing; Helms, B.A., Magdalene; Hulbert, B.A., Izard, B.A., C. Killick, B.A., and Knobel, B.A., Trinity; Linnell, B.A., H. Selwyn; Malim, Christ's; H. N. Matthews, St. John's; Micklethwait, B.A., Trinity; Mullings, B.A., Christ's; Murison, B.A., Trinity; Nixon, B.A., Gonville and Caius; Pearson, B.A., Emmanuel; Philbrick, B.A., and L Reynolds, B.A., Trinity; Scott, Christ's; Sellon, B.A., and Stiff, B.A., Gonville and Caius; Taylor, Downing; Timmins, B.A., Emmanuel; Topham, B.A., Christ's; Walker, B.A., King's; Walker, B.A., Clare; R. F C. Ward, St. John's; D. P. Watson, B.A., Trinity; West, B.A., Christ's; Whitmore, Gonville and Caius; Wilkinson, B.A., Pembroke; T. Wood, B.A., Gonville and Caius; and H. C. S. Woodward, M.A., Downing.

THIRD EXAMINATION.

Part I.

Allfrey, Trinity; B. H. Bell, Trinity; Coleman, St. John's; A. W. Daniel, Emmanuel; Deller, Trinity; Forbes, Christ's; Greg, Trinity; H. L. Gregory, St. John's; Harrison, Magdalene; Heilborn, Gonville and Caius; Irving, Gonville and Caius; Jephcott, Gonville and Caius; Lindsay, Sidney-Sussex; W. F. Lloyd, Clare; Lowe, Jesus; Mathias, Christ's; E. A. C. Matthews, Trinity; H. D. O'Sullivan, Emmanuel; Prest, St. John's; Roderick, Emmanuel; Rowland, Downing; B. H. Slater, Trinity; C. White, Christ's; E. A. Wilson, Gonville and Caius; W. R. Wilson, Corpus Christi; and Yeld, Trinity.

Part II.

A. M. Barraclough, Christ's; H. J. Bumsted, St. John's; F. P. Cayley, Trinity; H. G. Cooper, Emmanuel; Delbruck, King's; W. B. Dove, Christ's; W. B. Heywood, Emmanuel; Houseman, Clare; Hughes, Gonville and Caius; L. T. R. Hutchinson, Trinity; W. McDougall, St. John's; Mackenzie, Gonville and Caius; J. C. Muir, Emmanuel; W. Myers, Gonville and Caius; Pendlebury, Pembroke; Porter, Emmanuel; Robinson, Gonville and Caius; Stead, Gonville and Caius; B. R. Turner, Emmanuel; Twigg, Christ's; F. F. Ward, H. Selwyn; and Watson, Peterhouse.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, whose names are arranged in order of seniority as Members in accordance with the provisions of the Charter, having passed the necessary examination and conformed to the by-laws and regulations have been admitted Fellows of the College:—

Howse, Neville Reginald, L.R.C.P. Lond., London Hospital; diploma of Membership dated July 23rd, 1888.

Luard, Hugh Bixby, M.B., B.C. Cantab., L.R.C.P. Lond., Surgeon-Captain I.M.S., Cambridge University and St. Thomas's Hospital; Aug. 4th, 1887.

Kelly, Charles Ernest Mackenzie, M.B., B.S. Lond., L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester; July 30th, 1891.

Watkins-Pitchford, Wilfred, M.B. Lond., L.R.C.P. Lond., St. Thomas's Hospital; Nov. 12th, 1891.

Stack, Edward Hugh Edwards, M.B. Cantab., L.R.C.P. Lond., St. Bartholomew's Hospital; Feb. 11th, 1892.

Paterson, Herbert John, M.B., B.C. Cantab., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; Nov. 10th, 1892.

Hulke, Sydney Backhouse, L.R.C.P. Lond., Middlesex Hospital; Feb. 9th, 1893.

Wace, Cyril, L.R.C.P. Lond., King's College Hospital; July 27th, 1893.

Crowley, John Henry, M.B., B.S. Melb., Melbourne University and King's College Hospital; Feb. 8th, 1894.

Duffett, Henry Allcroft, L.R.C.P. Lond., Guy's Hospital; Feb. 8th, 1894.

Fox, George Raymond, L.R.C.P. Lond., St. Bartholomew's Hospital; May 10th, 1894.

Lee, William Edward, M.D., M.B. Lond., L.R.C.P. Lond., St. Bartholomew's Hospital; May 10th, 1894.

Drake, Courtenay Henry, M.B. Lond., L.R.C.P. Lond., St. Bartholomew's Hospital; Nov. 8th, 1894.

Gullan, Archibald Gordon, M.B. Lond., L.R.C.P. Lond., University College and Royal Infirmary, Liverpool; Nov. 8th, 1894.

Handley, William Sampson, M.D., M.S. Lond., L.R.C.P. Lond., Guy's Hospital; Feb. 7th, 1895.

Thomas, Thomas Morrell, M.B., B.S. Lond., L.R.C.P. Lond., Guy's Hospital; Feb. 7th, 1895.

Clark, William Gladstone, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; May 9th, 1895.

Legg, Thomas Percy, M.B. Lond., L.R.C.P. Lond., St. Bartholomew's Hospital; May 9th, 1895.

Cook, John Howard, M.B., B.S. Lond., L.R.C.P. Lond., University College Hospital; July 29th, 1895.

Going, Robert Marshall, M.B., B.Ch. Univ. Dub., L.R.C.P. Lond., Trinity College, Dublin, and London Hospital; Aug. 4th, 1896.

Twenty-two gentlemen were referred for six months and three for one year.

FOREIGN UNIVERSITY INTELLIGENCE.—*Algeria:* Dr. Brault has been appointed Professor of Tropical Diseases.—*Berlin:* The very important chair of Physiology lately occupied by the illustrious Professor du Bois-Reymond has been offered to Professor W. Th. Engelmann, of Utrecht, and accepted by him. He is a German both by birth and education. He has been, however, professor at Utrecht for the last twenty-four years. His contributions to physiology have been very numerous, especially researches on the action of muscle and nerve.—Dr. Paul Frosch, assistant in the Institute for Infectious Diseases, has been granted the title of Professor; a similar distinction has been conferred on Dr. Gustav Behrend, *privat-docent* of Dermatology.—*Budapest:* Dr. A. Irsai and Dr. A. Onodi, *privat-docenten* of Laryngology, have been promoted to Extraordinary Professorships.—*Naples:* Dr. Francesco Campione has qualified as *privat-docent* in Midwifery.—*Philadelphia (Medico-Chirurgical College):* Dr. Charles E. Sajous has been appointed Professor of Laryngology.—*Rome:* Dr. Enrico D'Anna has qualified as *privat-docent* in Surgical Pathology.

THE LIFE SAVING SOCIETY.—At the West India Docks, on July 3rd, at 3 P.M., the Life Saving Society will hold an international championship gala in the presence of T.R.H. the Duke and Duchess of York. In addition to the performance of the best amateur swimmers at home, representatives from Australia, New Zealand, America, Belgium, and Sweden have promised to take part in the display. The visitors will be entertained at the Holborn Restaurant at 7 P.M., when the distribution of prizes will take place by the acting President, the Hon. Sydney Holland. Tickets can be obtained at the offices of the Society, 8, Bayley-street, W.C.

PEKING HOSPITAL.—The annual report of the Peking Hospital in connexion with the London Missionary Society, 14, Blomfield-street, E.C., shows that during 1896 there were 26,000 attendances of male out-patients and 5000 of females; 362 visits were paid to patients in their own homes, and 174 men and women have been under more continuous treatment in the wards. The income was 992 Kung-fa taels (about £160) and the expenditure 902 Kung-fa taels (about £146); the average cost of each patient was 320 Peking cash, or about one penny. The operations included two amputations of the leg and one of the arm. The present annual report is the thirty-fifth; the medical officer is Dr. Eliot Curwen. The hospital provides ward accommodation for thirty-eight men and four women.

DIPHTHERIA IN LONDON.—In each of the weeks of the fortnight ended on Saturday last, the registered deaths from diphtheria in London were below the corrected decennial average for the corresponding periods of the years 1887-96. In the three weeks ended with June 12th the deaths from the disease registered in London had been 36, 33, and 39 respectively, but in the week next succeeding they fell to 29, and were 7 below the corrected average, 4 belonging to Limehouse, and 3 to Poplar sanitary areas. All the 29 deaths were of young persons aged under twenty years, 4 being of infants. In the outer ring the deaths from diphtheria were 7, including 3 in the Edmonton Union. In the following week, ended with Saturday last, June 26th, there were only 24 deaths from the malady registered in London, this total being 12 below the corrected average, 4 deaths belonging to St. Pancras, 4 to Camberwell, and 3 to Battersea sanitary areas. Again, all the deaths were of young persons aged under twenty years, none being of infants. The admissions to hospital during the week numbered 119, and 836 patients were still under treatment on Saturday last. In the outer ring the registered deaths from diphtheria last week numbered 8, of which 4 occurred in the West Ham union.

NATIONAL SOCIETY FOR EMPLOYMENT OF EPILEPTICS.—The annual meeting of Governors was held on June 30th at the offices, 12, Buckingham-street, Strand, the chair being taken by Mr. C. Montefiore Micholls. In the report presented by the Honorary Medical Staff a very satisfactory account is given of the improvement of the patients at the Society's "Colony" at Chalfont, both as regards the frequency and severity of their fits, while as regards their general health it is stated that without exception the condition of each "colonist" has materially improved. In the report of the executive committee reference is again made to the deplorable condition of the numerous applicants, who are compelled through lack of room to wait a long period for admission, and of whom one in every ten drops out of the list each year through insanity or death, while at the colony itself since its establishment in 1894 only one death has occurred and only one patient has had to be transferred to an asylum. The report concludes by pointing to future developments of the colony, for which special donations have been given or promised. These include a sanatorium for patients needing special care, another home for male "colonists," two homes for children, and a home for patients able to pay on a higher scale. But while so much help is forthcoming it is available, as the report points out, only for these special purposes; and as regards the general funds the position of the society is stated to be most serious and critical, and the committee make an urgent appeal to the charitable public for assistance, without which they will not be able to accept with safety the increased responsibilities which the before-mentioned developments will bring.

THE RE-ORGANISATION OF THE HEALTH DEPARTMENT IN BOMBAY.—Bombay is learning, says the *Times of India*, the lessons of the plague. An amendment of the Municipal Act is engaging the serious attention of the Government, and meanwhile the Municipal Commissioner has submitted a scheme for the re-organisation of the health department of that city.

PRESENTATIONS TO MEDICAL MEN.—At a meeting of the Federated Ball Committees of Portsmouth, held on June 9th, Mr. John Mulvany, L.R.C.P. Edin., Town Councillor, the chairman of the committee, received a presentation from his colleagues, as a token of their esteem, of a handsome gold medallion, enamelled with the red cross of St. John and the Borough Arms, with an appropriate inscription. The Ball Committees of the town federated for the purpose of organising a public ball in aid of the Mayor's Hospital Fund. The result was so satisfactory that the movement has been made permanent with a view to giving a charity ball every year. — Mr. B. Stewart Cowen, M.B. Glasg., of Charlton, Victoria, Australia, on the occasion of his leaving the district was the recipient from the residents of a handsome present.—Mr. Wm. C. Little, M.D. Ont., L.R.C.S. Edin., of Warracknabeal, Victoria, on his departure for Canada, was presented by the residents with a handsome travelling bag.—Mr. Reginald H. Noott, M.B. Edin., of the State Criminal Lunatic Asylum, Broadmoor, has received the gift of a handsome smoker's cabinet from the members of his psychological class. The male and female attendants who were successful in passing the examination made the presentation.—Mr. Wm. C. Faulkner, M.B. Edin., on resigning the position of resident medical superintendent to the Rockhampton Hospital, Queensland, was presented by the members of the nursing and working staff of that institution with an illuminated address and two cases containing dessert- and fish-knives and forks.—Mr. R. Bevan, L.R.C.P. Lond., D.P.H., was presented on June 11th by the Lydd, Kent, Ambulance Class with a malacca cane walking-stick suitably inscribed.—On June 25th last at the Cardiff railway station the employés of the Great Western Railway who have attended the recent lectures of the St. John Ambulance Association, presented Mr. Arthur Ernest Taylor, M.B., C.M. Edin., &c. with a tastefully worked, gilded, and oxidised inkstand, bearing a suitable inscription, in appreciation of his services as honorary lecturer to the class.—A valedictory banquet has been given to Mr. Hugh A. Deravin, M.B., Ch.B. Melb., of Pyramid Hill, Victoria, Australia, the residents also presenting him with an illuminated address.—Mr. Alfred J. Hamilton, L.R.C.P., L.R.C.S. Edin., of Mansfield, Victoria, Australia, has received a testimonial and purse of sovereigns from the residents of Mansfield, Jamieson, and Wood's Point, Victoria, on his leaving the district; and a complimentary banquet, presided over by the mayor of the borough, was given on April 27th last to Mr. A. E. Perkins, M.B., Ch.M. Syd., of Marrickville, near Sydney, New South Wales.

METROPOLITAN HOSPITAL SUNDAY FUND.

WE continue below our record of some of the principal amounts received at the Mansion House, the lists of which have been received at THE LANCET Office up to the time of our going to press on Thursday, when the total sum received amounted to £23,000. At the corresponding period last year the total was very nearly £31,500.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

THE ninth election of Fellows to fill the vacancies in the Council of the College under the new regulations, was held in the Library of the Royal College of Surgeons, Lincoln's-inn-Fields, on Thursday, the 1st inst., between 1.30 P.M. and 4 P.M. The result of the voting was as follows:—

	Votes.	Plumpers.
MR. EDMUND OWEN	323	28
MR. H. G. HOWSE	307	2
MR. RICKMAN J. GODLEE... ...	312	2
MR. W. WATSON CHEYNE... ...	290	7
DR. J. WARD COUSINS	259	9
MR. BENNETT MAY	236	6
MR. J. H. MORGAN...	236	5
MR. R. CLEMENT LUCAS	225	1
SIR W. B. DALBY	173	10
MR. ANDREW CLARK	104	8
MR. GEORGE JACKSON	89	5

Mr. Howse and Dr. Ward Cousins were therefore re-elected, and Mr. Owen, Mr. Godlee, and Mr. Cheyne elected members of the Council.

609 Fellows voted by proxy, 4 votes were received too late, and 4 were found to be invalid; 46 Fellows voted in person.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The London Water Question.

ON Monday, June 28th, the House of Commons gave a second reading to the Bill of the Government to strengthen the hands of water consumers in London in seeking redress of grievances from the supplying companies. In the debate which preceded the second reading Mr. Chaplin spoke of the Bill as a more or less temporary one, pending the report of the Royal Commission on the water supply of the metropolis.

Prisons Bill.

This Bill has been withdrawn by the Home Secretary on the ground that he saw no prospect of passing it during the present session.

Burial Grounds.

The Committee of the House of Commons on burial grounds began its inquiry at Westminster on Tuesday, June 29th, when it received from Mr. Adrian, Assistant Secretary of the Local Government Board, evidence as to the state of the law with regard to burial grounds and the powers and duties of the Local Government Board in the matter.

HOUSE OF COMMONS.

THURSDAY, JUNE 24TH.

Rural Postmen and Medical Advice.

Mr. Luttrell asked the Secretary to the Treasury, as representing the Postmaster-General, whether he would take steps to supply all rural postmen with free medical attendance in the same way as postmen in towns, or, in the event of the Department being unable to grant free medical attendance where there were not sufficient postmen to warrant the employment of a medical officer, whether an allowance could be paid to rural postmen when they had to seek medical advice.—Mr. Hanbury replied that rural postmen who resided in, or started from, a town where the Department had a medical officer were entitled to free medical attendance, and those who resided more than three miles from the town could obtain advice and medicine free at the surgery, but beyond this the Postmaster-General was not prepared to go.

Rabies.

Mr. Hazell asked the President of the Board of Agriculture whether he was aware that considerable dissatisfaction was felt at the order for the muzzling of dogs in the borough and county of Leicester upon the ground that there had been no proved case of rabies in that county for several years, and that the order would cause much inconvenience to the agricultural residents; and whether, under these circumstances, he could hold out any hope of an early revocation of the order.—Mr. Walter Long replied that he was aware that some dissatisfaction had been expressed at the inclusion of any portion of Leicestershire in the area in the Midlands to which muzzling orders had been applied, but in view of the fact that two cases of rabies had been reported during the last few months, and that there had been others in adjoining counties close to the Leicestershire boundary, he felt it his duty, in the interest of the extirpation of the disease from the country as a whole, to adopt the course which had been taken. He regretted that he did not see his way to the revocation of the order as suggested.

The London Water-supply.

On the report stage of the Southwark and Vauxhall Water Bill Mr. James Stuart moved to refer the measure back to the committee which had considered it. He said that for a number of years the quantity of water which had been drawn by the Southwark and Vauxhall Water Company from the River Thames had been considerably in excess of that which they were legally entitled to take from that source, and the Thames Conservators had consequently applied for, and had obtained, an injunction to restrain the company from continuing such illegal action, which injunction they had intimated they intended to enforce. The company had accordingly brought in a Bill to authorise them to legalise their overdraft in order that they might be enabled to supply the requirements of the poorer portion of the population of South London. The measure had been opposed on the ground that other water companies, if duly authorised by Parliament, were willing to supply the district in question with water. The London County Council were willing that a temporary measure should be passed which would authorise the company to obtain the water from the Thames which would enable them to meet the demands of the locality for an efficient water-supply; but they thought that the provisions of the Bill should be restricted to maintaining the *status quo* of the company until the Royal Commission now sitting to inquire into the whole subject of the water-supply of London had reported, and should not confer upon them any new powers of a permanent character. The measure, however, went further, and directed the company to bring in a new Bill next session which would confer new permanent powers upon them. To this proposal the London County Council decidedly objected, and he now proposed that the Bill should be re-committed to the former committee in order that the objectionable clauses should be struck out, and the measure converted into a strictly temporary one, merely preserving the *status quo* and regularising the action of the company until the Royal Commission should have made their report.—Mr. Rankin, one of the members of the committee, explained that he and his colleagues had passed the Bill in its present shape because in consequence of the injunction against the company having been obtained it was necessary that such a measure should be passed in order to prevent a water famine in the south of London. The committee were desirous that the measure should be a temporary one only, and if it were sent back to them they would have no objection to amend it in that direction.—Sir F. D. Dixon-Hartland, Chairman of the Thames Conservancy Board, said that the injunction against the company was granted to take effect at the end of twelve months, the interval being allowed to enable the company to come to Parliament and legalise their action and avoid the risk of water famine. The principle upon which the Thames Conservancy proceeded was this, that there was ample water in the Thames for the whole of London, but the companies must take it in a proper way in the winter months and store it in reservoirs, not withdrawing it in the summer against the interests of navigation when the water was low. If the House re committed the Bill now it would in all probability tend to the loss of the Bill, and for the danger of a water famine next year the House would be responsible.—Mr. Stuart Wortley assured the House that the only desire of the company was to legalise their position and to secure power to supply their customers.—Mr. Chaplin said that as President of the Local Government Board he dare not take the responsibility of action which might contribute to a water famine in South London next summer, and if the motion were pressed to a division he must vote against it.—After some further discussion Mr. Stuart asked and obtained leave to withdraw his motion.

FRIDAY, JUNE 25TH.

Boarding out Pauper Children.

Lord Edmund Talbot asked the President of the Local Government Board whether, in November, 1881, the Local Government Board decided that the boarding-out orders did not refer only to children boarded out by the guardians from the workhouse, but whenever the guardians granted out-relief to a child living with a person not legally liable for its support, that that child would come under the said orders.—Mr. T. W. Russell, who replied for the President, said that he had no doubt that the Local Government Board expressed the opinion as stated in the question with reference to the effect of the order issued in 1877 as to boarding out, but as there was some doubt on the subject the order subsequently issued in 1889 was in consequence somewhat differently worded as regards this matter.

MONDAY, JUNE 28TH.

Remarkable State of Things in Ireland.

Mr. Gerald Balfour, Chief Secretary for Ireland, said, in reply to a question by Mr. Crilly with regard to the state of affairs in the Union of Belmullet, that on May 12th Mr. Lavan, the dispensary medical officer, reported that sixteen cases of fever had occurred on the Inishkea Islands in this Union, and he attributed the cause of the outbreak to the islanders' habit of keeping cattle and sheep in their houses and having cesspools at their doors. The Local Government Board thereupon directed the medical officer to furnish weekly reports as to the progress of the sick and as to the precautions taken to prevent the spread of the disease. On May 30th he reported that the sixteen cases were those of people in good circumstances and not fit subjects for poor relief. The Board informed him that whether they were subjects for relief or not he should visit the houses and see that all necessaries were supplied and that disinfection was properly carried out. On June 3rd Mr. Lavan reported the type of fever to be very mild, that the disease appeared to be on the decline, and that he had thoroughly disinfected the houses. On June 7th he reported that, with the exception of a few people on the islands who were destitute, the rest were in fairly good circumstances, but that they laboured under the impression, which it was difficult to remove, that fever patients should be given nothing but cold water. The destitute were provided with all necessary nourishment and stimulants; and the services of two trained nurses from Dublin were requisitioned in addition to two local nurses. Three of the patients had died, and removal of the sick to the hospital on the mainland was out of the question. The trained nurses were landed on June 11th. On June 22nd the medical inspector of the Local Government Board visited the islands in company with Mr. Lavan. He stated that there were thirteen cases of fever of different kinds on the south island, but that the north island was free from fever. The inspector considered that the attendance on the nursing of the sick had been sufficient up to the present. He also attended a meeting of the board of guardians and pointed out to them that it was imperative on them to enforce measures for lime-washing, cleansing, and disinfection of all infected houses, and that the remedies must be continued until satisfactory results were attained. The guardians recognised their responsibilities as the sanitary authority, and were taking measures to comply with the inspector's recommendations. He (Mr. Balfour) was not aware of any famine on the island, nor could the outbreak of fever be attributable to any want of food.

TUESDAY, JUNE 29TH.

Corporal Punishment in Prisons.

Sir Matthew White Ridley, in answer to Mr. J. A. Pease, said that during the last six years forty-four prisoners in local prisons in the United Kingdom and twenty in convict prisons had received corporal punishment twice, and six in local prisons and seven in convict prisons had received it more than twice during the same period. Mr. Brodrick, in reply to Mr. Pease, said that during this period eighty-two prisoners in military prisons abroad received corporal punishment. One prisoner in the military prisons at home was twice corporally punished, but returns on this point from the prisons abroad had not yet been received.

WEDNESDAY, JUNE 30TH.

Plumbers' Registration Bill.

This sitting of the House was occupied with the discussion of the Plumbers' Registration Bill as amended by the Standing Committee. A motion was made to throw out the Bill, but it was rejected by 200 to 77 votes, and thereafter some progress was made with the consideration of the amendments to the clauses. Strong objection was taken in several quarters to the machinery of the Bill.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

AITKEN, WM. B., M.B., Ch.M. Glasg., has been appointed Senior Resident Surgeon to the Women's Hospital, Melbourne, Australia.

BEATTIE, ROBERT M., M.B., Ch.M. Edin., has been appointed Medical Superintendent to the Lunatic Asylum, Auckland, New Zealand.

BETHELL, A., M.R.C.S., has been appointed Medical Officer by the Bridgnorth Rural District Council.

BOWKER, ROBERT S., M.R.C.P. Lond., L.R.C.P. Edin., M.R.C.S. Eng., has been appointed an Honorary Surgeon to the Sydney Hospital, New South Wales.

COATES, J. MANDALL, M.B., C.M. Edin., has been appointed Assistant House Surgeon to the Northern Hospital, Liverpool.

COOK, H. W. I., M.B., Ch.B. Durh., has been appointed Officer of Health for Winchelsea Shire, Victoria, and a Public Vaccinator at Birregurra, Victoria, Australia.

COX, FRED. H., M.B., Ch.M. Syd., has been appointed a Medical Officer for the Hospital at Goodooga, New South Wales.

DENNEHY, P. R., L.R.C.P. Irel., L.R.C.S. Edin., has been appointed Medical Officer for the Lismore Dispensary District.

EATON, J., M.D. Glasg., F.F.P.S. Glasg., has been re-appointed Medical Officer of Health for the Cleator Moor Sanitary District of the Whitehaven Union.

EGCLES, W. MCADAM, M.S. Lond., F.R.C.S. Eng., has been appointed Examiner in Anatomy to the Society of Apothecaries of London.

EDWARDS, H. N., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Markyate Sanitary District of the Luton Union, vice F. W. D. McGachen, resigned.

FLEETWOOD, THOS. F., M.B. Dubl., L.R.C.S. Irel., has been appointed Officer of Health for Warrnambool Town, Victoria, Australia.

FOX, HERBERT, M.B. Lond., has been appointed Junior Medical Officer (*pro. tem.*) to the Fisherton House Asylum, Salisbury.

GEE, T. ERNEST, F.R.C.P. Edin., L.R.C.S. Edin., L.S.A., F.C.S., has been appointed Honorary Anæsthetist to the Hospital for Epilepsy and Paralysis, Regent's-park.

GOODE, ARTHUR, M.B., B.S. Adel., has been appointed a Medical Officer for the Local Board of Health, Dundas, Western Australia.

GREIG, WM. C., M.B., Ch.M. Edin., has been appointed an Assistant Medical Officer for the Lunatic Asylum, Seacliff, New Zealand.

HAGENAUER, A. G., M.B., Ch.B. Melb., has been re-appointed a Medical Officer to the Women's Hospital, Melbourne, Australia.

HARBISON, WM. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer for the Destitute Poor and Aborigines at Georgetown, South Australia.

HARGREAVES, J. A., M.B., C.M. Aberd., has been re-appointed Medical Officer of Health by the Wetherby Rural District Council.

HILL, ALFRED W., M.D. Brux., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed a Member of the Central Board of Health, South Australia.

HOWARD, ARTHUR DASHWOOD, B.A. Cantab., M.D. Brux., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed District Medical Officer for the Parish of Hampton Hill.

JOHNSON, JOS. H., M.B., Ch.M. Edin., has been appointed Officer of Health for Alexandria Shire, Victoria, Australia, and a Public Vaccinator for Alexandria.

JOHNSTON, J., M.B., Ch.M. Glasg., has been appointed a Junior Medical Officer for the Lunatic Asylums Department, Victoria, Australia.

KEENAN, T. F., M.B., B.S. Durh., has been appointed Medical Officer for the Feragh Dispensary District of the Carrickmacross Union.

KELLY, HORACE G., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Officer of Health for the Shire of Gordon, Victoria, Australia.

LOW, CHAS. W., M.B. Durh., L.R.C.P. Lond., D.P.H., M.R.C.S. Eng., has been appointed Medical Officer of Health by the East Stow Rural District Council.

MCCOMB, WM. T., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Borough of Beccles.

MOLE, HAROLD FREDERICK, F.R.C.S. Eng., L.R.C.P Lond., has been appointed House Surgeon and Senior Resident Officer at the Bristol Royal Infirmary.

MORIER, CHAS. G. D., L.K.Q.C.P. Irel., L.R.C.S. Irel., has been appointed a Medical Officer for the Destitute Poor and Aborigines at Mount Barker, South Australia.

PEARCE, F. H., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician to the Northern Hospital, Liverpool.

PERRY, W. D., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed a Relieving Medical Officer to the Lunatic Asylums of the Colony of New Zealand, as occasion requires, and Assistant Medical Officer for the Lunatic Asylum at Wellington, New Zealand.

PLAYER, CHAS. R., M.B., Ch.B. Melb., has been appointed a Public Vaccinator at Sunbury, Victoria, Australia.

PURSLOW, C. E., M.D. Lond., M.R.C.P. Lond., has been appointed Ingleby Examiner, Mason College, Birmingham, for the ensuing year.

RENDLE, RICHARD, F.R.C.S. Eng., has been appointed House Surgeon to the Knowle Hospital, Freemantle, Western Australia.

RITCHIE, ROBERT H., M.B., Ch.B. Melb., has been appointed a Surgeon to the Horsham Hospital, Victoria, Australia.

RUTTER, G. F., M.B., Ch.M. Syd., has been appointed Registrar and Pathologist for the Sydney Hospital, New South Wales.

SCOTT, JOHN A., M.B., Ch.M. Edin., has been appointed Assistant Resident Surgeon to the Women's Hospital, Melbourne, Australia.

STEPHENS, L. B. W., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Havant Union, vice T. P. Stephens.

TALBOT, ALFRED G., M.B., M.S. Edin., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed a Resident Surgeon for the Nelson Hospital, New Zealand.

TAYLOR, P. C. P., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed as Surgeon and Agent to the Admiralty for the Hastings and St. Leonards District.

WATSON, GEORGE G., M.B., Ch.M. Edin., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator at Warracknabeal, Victoria, Australia.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

BOROUGH OF SHREWSBURY.—Medical Officer of Health. Salary £200 per annum. Applications to the Town Clerk, Guildhall, Shrewsbury.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Assistant Physician.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—House Surgeon and Assistant House Surgeon for twelve months. Salary of the House Surgeon £100 per annum, with furnished apartments, board, and washing. That of the Assistant House Surgeon £50 per annum, with furnished apartments, board, and washing.

Digitized by Google

DISTRICT ASYLUM, Mullingar.—Medical Woman as Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, furnished apartments, attendance, and laundry.

GENERAL INFIRMARY AT GLOUCESTER AND THE GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeon for six months. Board, residence, and washing provided.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Senior House Surgeon for six months. Salary at the rate of £60 per annum, with board, lodging, and washing in the hospital. Also Junior House Surgeon for six months. Board, lodging, and washing in the hospital.

HULL ROYAL INFIRMARY.—Junior Assistant House Surgeon for one year. Salary £40, with board and lodging.

LONDON HOSPITAL MEDICAL COLLEGE, Turner-street, Mile-end, E.—Demonstrator of Biology. Salary £75 per annum.—Bacteriologist to the Hospital, and Lecturer on Bacteriology and Pathological Chemistry.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Assistant Resident Medical Officer for six months. Residence, board, and lodging are provided, and an honorarium given at the termination of the appointment.

LONDON THROAT HOSPITAL, 204, Great Portland-street.—Two Assistant Surgeons.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer, unmarried, for one year. Salary £150 per annum, with board and residence.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer for six months. Salary at the rate of £30 per annum, with board, attendance, and washing.

PLYMOUTH BOROUGH ASYLUM.—Locum Tenens from July 8th to 23rd. Terms three guineas weekly, with board, &c. Applications to Dr. Davis, Blackadon, Ivybridge.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon for six months. Board, lodging, and washing provided.

ROYAL HALIFAX INFIRMARY.—House Surgeon, unmarried. Salary £80 per annum, advancing £10 per year up to £100, with residence, board and washing.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE, London, E.C.—Demonstrator and Assistant Demonstrator of Chemistry.

ST. GEORGE, HANOVER-SQUARE, PROVIDENT DISPENSARY, Little Grosvenor-street, W.—Resident Medical Officer. Salary £100, with allowances, about £30, and residence at the Dispensary.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Assistant Lectureship on Chemistry and Physics. Salary £100, rising to £125.

TOTTENHAM HOSPITAL.—Assistant Surgeon.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Surgeon.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Assistant House Surgeon, for six months. Board, lodging, and washing provided.

Births, Marriages, and Deaths.

BIRTHS.

APPERLY.—On June 24th, at Redhill, the wife of Herbert Apperly, L.D.S. M.C.S. Eng., of Chandos-street, Cavendish-square, W., of a son.

BOWMAN.—On June 21st, at Ulverston, the wife of R. O. Bowman, M.D., of a son.

EDRIDGE-GREEN.—On June 23rd, at Ravensfield-villas, Hendon, N.W., the wife of F. W. Edridge-Green, M.D., F.R.C.S., of a son.

FOTHERINGHAM.—On June 23rd, at Skelmorlie, Ayrshire, the wife of M. B. Fotheringham, of a son.

HOFFMAN.—On June 21st, at Goddenden, Farnborough, Kent, the wife of Arthur H. Hoffman, L.R.C.P., L.R.C.S. Edin., of a daughter.

VISICK.—On June 26th, at Brownswood-park, N., the wife of Hedley C. Visick, M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

DRURY—RITCHIE.—On June 19th, at St. Anne's, Wandsworth, by the Rev. Norman Campbell, W. H. Drury, L.R.C.P. Edin., &c., of Otley, Yorkshire, to Maie, third daughter of the late Dr. Ritchie, Otley, and Mrs. Ritchie, Wandsworth.

HOOPER—WILLS.—On June 28th, at All Saints', Highgate, George H. Hooper, M.R.C.S., L.R.C.P., to Kate Haydon, youngest daughter of T. Haydon Wills, of Highgate.

WILSON—WHITE.—On June 24th, at All Saints, Kenley, Surrey, Norman O. Wilson, F.R.C.S., of Kingston-hill, to Margaret Louise, fifth daughter of George T. White, of Malvern, Kenley.

DEATHS.

DORAN.—On June 23rd, at Mill-road, New Brompton, Kent, James Doran, M.D., late 2nd Battalion 60th Royal Rifles.

ENGLAND.—On June 25th, at Pencester-road, Dover, Richard Edward England, M.D.

HOOD.—On June 25th, at Laleston Cottage, near Bridgend, Archibald Hood, M.B., aged 36 years.

LEWIS.—On June 19th, at West Malling, Charles Lewis, M.R.C.S., L.S.A., formerly of Sandgate-road, Folkestone, in his 51st year.

READE.—On June 23rd, at Sunnylands, Park-gardens, Bath, Surgeon-General Herbert Taylor Reade, C.B., V.C., Hon. Surgeon to the Queen.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, is given in this number of THE LANCET. It is intended, in future, to include the Index and Title page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers will also be ready in a few days. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

PELLAGRA?

To the Editors of THE LANCET.

SIRS,—Would any of your readers kindly inform me if the case described below is one of pellagra? Owing to the fact that my interpreter was not particularly well up in either English or modern Greek, I was unable to learn as much as I wished about the history, &c., of the patient.

A healthy-looking woman brought her child, a little girl aged four years, on board for treatment and showed me a slightly elevated flat patch a little below and behind the left ear. The diseased part was pale in colour, and, I think, confined to the skin. It appeared to be painless, and contained about a dozen apertures filled with hard, yellowish matter. The whole patch was about an inch in diameter, and each orifice about one-tenth of an inch. The mother stated that the child, although four years old, could neither speak nor walk; that the illness had been of only eight months' duration; that many other patches like those described had appeared on the head and face, and after a time had disappeared. I examined one cicatrix on the bridge of the nose; the colour was like the surrounding parts, with which it was also level, but it was dotted all over with small pin-point punctures, from which there was no discharge. Beyond the facts mentioned above this child appeared to be in perfect health. Skin, nails, and glands appeared normal. Although the child could not speak or walk she did not seem to be in the least idiotic.

I have since met with another case of the same kind at another village in Crete, but this time the child spoke and walked.

I am, Sirs, yours faithfully,

Crete, June 23rd, 1897. VAGAMUNDO.

"A GOOD WAY BACK."

To the Editors of THE LANCET.

SIRS,—If your correspondent, Mr. W. T. Lynn, writing from Blackheath, will refer to vol. ii. of THE LANCET, 1832 and 1833, pp. 186 and 187, he will not only find a biographical sketch of the life of his father's uncle (William Lynn), but also a likeness of him, which, if as good as that of Sir Charles Bell in the same volume (whose lectures my late father attended, and he told me that it was a first-rate likeness), must be a very good one.

I am, Sirs, yours faithfully,

Allendale, Northumberland, June 26th, 1897. GEORGE ARNISON.

Practitioner.—1. It is now believed by the best authorities that the poison of scarlet fever when conveyed to a puerperal patient produces scarlet fever and not puerperal septicæmia. "Practitioner" speaks, however, of "any infectious disease." We should say that it would be highly dangerous to attend confinements while attending cases of erysipelas or diphtheria. Though we believe satisfactory disinfection of the attendant to be perfectly possible, it would involve much care, trouble, and time to make it really efficacious. Practically, therefore, it is better not to attend lying-in cases when attending such infectious cases. 2. There are several oils of erigeron. We presume our correspondent refers to Erigeron Canadense, or Canadian flea-bane. This has been used as an internal hæmostatic. Our correspondent should consult the "Real-Lexicon der Medicinisch-Pharmaceutischen Naturgeschichte und Rohwaarenkunde" and the Proceedings of the American Pharmaceutical Association (Vol. XIV.). The physiological action is that of oil of turpentine, but less irritant. 3. There is no objection at all to the dilution. A mixture of equal parts by weight of glycerine and water is probably the best preservative known for vaccine lymph.

GOOD ADVICE.

WE extract the following from the *Canadian Journal of Medicine and Surgery* for June, 1897. The verses are in the nature of a suggestion to a brother editor in his treatment of a recent voluminous correspondence, but although topical their wisdom is of universal application. The most usual blemish in the communications which reach us is diffuseness, and although we do not hold in its entirety with the editorial "boiling down" recommended in the verses, without some such process many useful papers would not see the light. As it is, diffuseness remains by far the most frequent cause of rejection.

If you've got a thought that's happy,
Boil it down;
Make it short, and crisp, and snappy,—
Boil it down.
When your brain its coin has minted,
Down the page your pen has sprinted,
If you want your effort printed,
Boil it down.
Take out every surplus letter,—
Boil it down.
Fewer syllables the better,—
Boil it down.
Make your meaning plain,—explain it
So we'll know, not merely guess it;
Then, my friend, ere you address it,
Boil it down.
Boil out all the extra trimmings,—
Boil it down;
Skim it well, then skim the trimmings,
Boil it down.
When you're sure 'twould be a sin to
Cut another sentence into,
Send it on, and *we'll* begin to
Boil it down.

F. K.—The climate is extreme, summer being bright and hot and winter long and cold. The island is mountainous, well-timbered, and salubrious, but a very delicate person should not be sent there, as the comforts of life may not be easy to obtain and the conditions of life are necessarily a little rough. We know of no book giving exact information, but think our correspondent might write to one of the medical men settled there.

THE TREATMENT OF WRITER'S CRAMP.

To the Editors of THE LANCET.

SIRS,—Would any of your readers be good enough to give me hints as to treatment which has been found beneficial in "writers' cramp" beyond that of rest and general hygiene?

I am, Sirs, yours truly,

Beyrout, Syria, June 21st, 1897. SCRIBO, M.D.

"AN APPLIANCE FOR THE DEAF."

IN reply to "J. W. W." in THE LANCET of June 26th, Messrs. W. H. Bailey and Son, of 38, Oxford-street, write to say that they manufacture an ear trumpet of the nature indicated by our correspondent which, though not made of aluminium, is very light. The appliance leaves the hands quite free.

Digitized by Google

WANTED SUGGESTIONS FOR TREATMENT.

To the Editors of THE LANCET.

SIRS,—I have a case of progressive muscular atrophy which has, so far, only attacked the limbs of my patient, who is forty-five years of age, and otherwise in good health. I have been using subcutaneous injections of strychnine, which, while they appear to have stopped the disease attacking the trunk, have in no way prevented the gradual but steady loss of power in his limbs. Can any of your readers suggest anything further? I am, Sirs, yours faithfully,

June 30th, 1897. F.R.C.S.

L.R.C.S. will find in "Hygiene for Beginners" by Reynolds, and published by Messrs. Macmillan and Co., Limited, the kind of information he requires.

THE GROWING INCREASE IN THE USE OF DRUGS IN THE UNITED STATES.

"IN America," writes a correspondent, "there are more drugs taken than in any other part of the world. The consumption of patent and proprietary medicines is enormous. Happily for the health of the inhabitants at large many of these are more or less harmless, but of late years a most alarming increase has occurred in the use of deleterious drugs. Opium, cocaine, and chloroform are stated by those competent to speak with authority to be used on a very large scale. The habit is increasing with females at a much more rapid rate than with males, and is giving rise to alarm throughout the country. The fault for this state of affairs is by many laid at the door of the medical man. It is asserted that it is through his prescriptions that the victims of the habit first acquired the taste which eventually developed into a perverted appetite. On the other hand, the majority of physicians strenuously deny that such is the case now, although they admit the fact that sufficient care was not taken in this respect in bygone days. At the present time among all practitioners of experience great discretion in prescribing is observed, and a wise intolerance has grown up of the careless methods of the past, when the harmful effects that might result had not become so exactly ascertained or so widely recognised. A cure is shunned which may be followed by something far worse than the original disease, and except when such treatment is absolutely indicated the use of powerful opiates is avoided. Nevertheless, the disastrous truth remains that narcotism in all forms is greatly on the increase, and if the medical profession are not to be held accountable for spreading the evil the cause must be looked for in some other direction. This cause, probably lies between the general public and the laxity of the laws in reference to the sale of dangerous drugs. With the general public it is the case of a little knowledge. Everyone in these days knows something of the action of many drugs, particularly of the dangerous ones, and if a person suffers from a pain or some slight complaint, advice is quickly given by friends to try a remedy which has relieved them in a like situation. As for the drug stores, the law prohibiting the sale of dangerous drugs is practically a dead letter, so easily can it be evaded; and there are few shops where almost any poison cannot be bought without the authority of a physician. Some of the proprietary medicines, too, contain anodynes and intoxicants, so that it is possible for the morphine habit, liquor habit, or cocaine habit to be developed unconsciously. This is a danger to which children are especially subjected. Many of the soothing compounds contain opium, and a latent tendency can be instilled into a child which may break out into a strong passion at the first legitimate contact with the drug. As in all countries, it is the very poor and the very rich who are most addicted to the use of drugs and intoxicants. The native-born American woman is from her mode of life and habits more highly strung and neurotic, probably, than women of any other race, and in consequence falls an easier prey to the slavery of narcotism."

Tibia.—If the assistant's agreement is so worded, practice at a future date can be barred within a reasonable radius. It is a matter of the wording of the agreement, and the assistance of a solicitor should be obtained.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—Can any of your readers assist me to find an institution to receive the following case for a small payment of £13 per annum—a woman, aged forty-one years, daughter of a tradesman, who has been in an institution for unmanageable women for the past two years, but has been discharged as she is so obstreperous. She fights with the inmates and incites them to mischief, and cannot be controlled where she is. Her health is excellent, and she can do any amount of hard work. I am, Sirs, yours faithfully,

W. H. WILLIAMS.

The Cedars, Sherborne, Dorset, June 27th, 1897.

COLONIAL REGISTRATION.

To the Editors of THE LANCET.

SIRS,—Is it necessary or advisable to become registered as a "colonial practitioner" previously to going out to South Africa (with special reference to the country about Kimberley, Mafeking, and Buluwayo)? If so, will you be good enough to give me such information as to how and where I am to do so. I have already written to the General Medical Council Office, but they are unable to supply any information there.

I am, Sirs, faithfully yours,

June 29th, 1897. C. F. H. W.

"*" Persons desirous of practising in Kimberley and Mafeking should make written application to the Secretary, Colonial Medical Council, Colonial Secretary's Office, Capetown. In the case of Buluwayo written application should be made to the Administrator, Salisbury, Rhodesia. The applications should be accompanied by the original diplomas, together with sworn declarations of identity. The licence to practise in either colony is £5.—ED. L.

Catheter.—The best lubricant for gum elastic catheters is a solution of perchloride of mercury in glycerine 1 in 1000. To keep them aseptic when not in use they should be stored in a jar containing either a 1 in 1000 solution of perchloride or a 1 in 20 solution of formalin, as bought. The commercial solution of formalin is a 40 per cent. solution. Even with these solutions, however, the catheters do not last long.

A SALUBRIOUS STATION.

ALTHOUGH it is not clear whether the *νησοι μακαρων*, or Islands of the Blest, of the ancients were the Cape Verde or the Canaries, the claim of the latter to rank as one of the most salubrious portions of the world receives strong confirmation from the vital statistics of the Spanish troops who are fortunate enough to be stationed there. It would probably be difficult to excel, or even to equal, the following figures taken from the last annual report (the rates for the entire army are shown in brackets):—Admissions to hospital, 288·75 per 1000 of strength (443 82, not including slight cases); typhoid fever, *nil* (6·96); pulmonary tuberculosis, 2 84 (7 42); pneumonia, *nil* (12 10); paludism, *nil* (15 57); syphilis, 0 95 (11·36); venereal affections, 55·60 (71·80); small-pox, *nil* (3 09); death-rate, 0 96 (8 41).

H. A. C. is entitled to proper payment for his services. There is no onus upon the principal in question to call, although to do so would be usual.

COMMITTAL OF A QUACK.

AN inquiry into the circumstances attending the death of Miss Elizabeth Blacker, of Grange Farm, near York, has recently been held by the York district coroner, with the result that a quack has been committed for trial in custody. The evidence at the inquest showed that the deceased was the victim of malignant disease of the breast, and that she had been treated by a person of the name of F. C. Hudson. The jury found that death was due to poisoning by arsenic absorbed into the system from a plaster applied by Hudson. Hudson, who gave evidence, said his name was W. L. Watson, and gave an address in the Adelphi, London. He was, as we have said, taken into custody and committed for trial.

P. C. S.—The communication loses its authority by not having the name and address of the writer appended.

ERRATUM.—In our issue of June 12th we announced that Mr. Edwin Arthur Gibson, M.B., C.M., had been admitted a Fellow of the Faculty of Physicians and Surgeons of Glasgow. The gentleman so elected was Mr. John R. Gibson.

During the week marked copies of the following newspapers have been received:—*Devon Gazette, Derby Daily Telegraph, New Zealand Herald, South Wales Daily News, Scotsman, Dundee Courier, North Eastern Daily Gazette, North Devon Herald, Birmingham Gazette, Newcastle Journal, Times of India, Pioneer Mail, Sheffield Daily Telegraph, Builder, Leicester Post, Sussex Daily News, Bradford Observer, Leek Times, Pulman's Weekly News, Architect, Liverpool Daily Post, Western Morning News, Leamington Advertiser, Manchester Courier, Bristol Mercury, Citizen, Yorkshire Post, Coventry Times, Lowestoft Standard, Huddersfield Examiner, Leeds Mercury, Worcester Daily Times, Coalville Times, Darwen News, Sanitary Record, Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, City Press, Mining Journal, Local Government Chronicle, Rangoon Times, Local Government Journal, Australian Medical Gazette, Surrey Advertiser, Newbury Weekly News, Royal Cornwall Gazette, Durham City Advertiser, Ormskirk Advertiser, Kelso Mail, Glasgow Evening News, Ilfracombe Gazette and Observer, New York Herald (Paris), West Briton Advertiser, Le Temps (Paris), Weekly Sun, Walsall Advertiser, Western Mail, Jackson's Oxford Journal, Heywood Advertiser, Garston Weekly News, Chesham Examiner, &c., &c.*

The Croonian Lectures

ON

THE MEANS BY WHICH THE TEMPERATURE OF THE BODY IS MAINTAINED IN HEALTH AND DISEASE.

Delivered before the Royal College of Physicians of London, on June 15th, 17th, 24th, and 29th,

BY W. HALE WHITE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT, GUY'S HOSPITAL.

LECTURE IV.[1]

Delivered on June 29th.

MR. PRESIDENT AND GENTLEMEN,—The third method which has been used in the study of the amount of heat produced under different conditions may be called the chemical. It need not detain us long, for the study of the chemistry of the heat-production of the body is so beset with difficulties that up to the present time not very much work has been done at this subject. There are two divisions of it—namely, the chemistry of the heat-production in the non-febrile and in the febrile states, and we will consider them in that order.

The breaking down of any chemically complex substance, such as a proteid or a fat, always leads to the liberation of energy. Various observers have, by burning these substances in a calorimeter, calculated the amount of heat set free by their destruction. In such a case the whole of the liberated energy appears as heat. Some of the most careful and recent results are Stohmann's.[2] His figures are gramme calories, and they represent the amount of heat necessary to raise one gramme of water from 17° to 18° C. They are shown in the following table.

TABLE XXVII.

—	Gramme calories.
The heat value of one gramme of most albumins is	5298 to 5941
The heat value of one gramme of meat is...	5662
The heat value of one gramme of albuminoids is	4650 to 5961
The heat value of one gramme of chondrin is	5130
The heat value of one gramme of animal fat is	9509
The heat value of one gramme of olive oil is	9500
The heat value of one gramme of carbohydrates is...	4381 to 3714
The heat value of one gramme of cane sugar is	3955

These figures are, as we shall see in a moment, of great value; but I need hardly remind you that we cannot calculate the heat production of an animal from its diet. In the first place we do not know what proportion of any meal is absorbed from the gastro-intestinal tract; secondly, not all the energy set free in the body is manifested as heat; some takes the form of mechanical work, and therefore in calculating the heat value of any particular diet we should have to deduct the energy which in the body takes the form of motion; but this is very difficult to estimate accurately, and therefore the deduction to be made from the total heat value of the food would be uncertain; and, thirdly, the food may be stored up in the body and not broken down for some time. The value of figures, like those of Stohmann, which show the amount of heat produced by the breaking down of the albumins and fats of the body lies in the fact that we can, by observing the amount of nitrogen and carbon excreted, calculate what must have been the amount of proteid and fat which had to be broken down to produce these amounts of nitrogen and carbon, and then, by looking at Stohmann table, we find how many calories the breaking down of these proteids and fats gave rise to. But in these calculations we must remember that although the fats are completely broken down yet the proteids are not. Nearly all the proteid is, however, broken down to urea and uric acid; the excretion of these can be measured and the number of calories resulting from their complete destruction estimated; if this is done and the calories of energy remaining in the urea and uric acid are deducted from those set free if a gramme of albumin is broken down as low as possible, we, of course, easily obtain the energy value to the body of a gramme of albumin, and this is found to be about 4000 gramme calories.

Rubner[3] has in animals, by careful analysis of the expired air, the urine, and the fæces, observed the amount of nitrogen and carbon excreted, from which he calculates the quantity of each in proteids and fats, which corresponds to such an amount of nitrogen and carbon. Then he compares the heat given off by the animal to an animal calorimeter with the heat that he would, from his knowledge of the number of calories set free by the breaking down of these quantities of proteids (after allowance for the urea and uric acid) and fats, expect to be produced by the animal during the time it was in the calorimeter. Table XXVIII. shows how the calories

TABLE XXVIII.

Diet.	Number of days.	Total of calculated heat.	Total of heat estimated by calorimeter.
Starving	5	1296·3	1305·2
	2	1091·2	1056·6

	6	2249·8	2276·9
Meat	7	4780·8	4769·3

reckoned by each method correspond. It gives in kilogram me calories the results of experiments on a small dog which was observed for five days starving, five days on a fat diet, eight on a diet of meat and fat, and six on meat; and on a big dog observed two days starving, twelve days on meat and fat, and seven on meat. Each twenty-four hours was observed separately, and the table gives the total results for each dog for each diet. Rubner's experiments are very carefully performed, and therefore we must all look forward with great interest to their confirmation. If they are confirmed they will prove that he has successfully overcome many great difficulties, and the agreement between his chemical and calorimetrical results will be remarkable, for, firstly, we have seen that animal calorimeters may be very inaccurate instruments and unless very carefully constructed will give rise to all sorts of errors. Secondly, the chemical method gives the heat produced, but the calorimeter only indicates that lost, and I have in the last lecture shown that we cannot infer quite accurately from that the amount produced by the animal, for we do not know whether during the experiment it varies its rate of loss, and, further, we cannot tell, unless we know the variations of its temperature during the twenty-four hours an experiment lasted, how much of its heat production has been expended in raising its temperature, and if any has been so used it would not be shown by the calorimeter. In these experiments the dissipation of energy as mechanical motion does not interfere with the results, for the animals keep quiet in a cage which just fits them; and, further, such mechanical work would tell equally in both sets of figures, as also would the work done by the heart and respiratory muscles, most of which work becomes heat as it has to overcome friction.

We now pass on to a consideration of the experiments in which an attempt has been made to calculate the heat production of starving animals suffering from fever by observing the amount of nitrogen and carbon excreted. It is always necessary to use starving animals, for it is well known that

[1] Lectures I., II., and III. were published in THE LANCET of June 19th and 26th and July 3rd respectively.

the ingestion of a meal increases the production of heat, as, indeed, the table just quoted from Rubner shows. This method can give us some idea of the chemical processes involved in fever, but in applying the results to man we must remember that as human patients are given food during a febrile illness, and as man has, by his sweating and hairless skin, far better means than the lower animals of varying his loss of heat, the processes may be somewhat different in man from the processes in a starving animal. By far the best experiments are those of May,[4] and I am the more disposed to quote some of his results as I found when Professor Burdon Sanderson's article on Fever in Professor Clifford Allbutt's System of Medicine appeared that the high opinion I had formed of their value was confirmed. May begins by giving a history of the subject, and comes to the conclusion that the balance of evidence is that in febrile pyrexia the respiratory quotient is unaltered, that the excretion of CO_2 is not much increased, and that the brunt of the destruction falls on the proteids. He used rabbits in whom he induced swine erysipelas. For some days before the production of this fever they were starved so as to get their excretion of urea steady, and during the fever May most carefully observed the output of nitrogen and carbon both in the urine and the breath for more than twenty hours at a time, and he calculated what must have been the original amount of proteid and fat tissue which would, when broken down, correspond to the nitrogen and carbon he found excreted. Using Stohmann's heat values of proteid and fat, he was able to estimate the number of calories which would be set free by the destruction of these amounts of proteids and fat. The following experiment may be quoted (Table XXIX.). It shows distinctly that when a starving

rabbit is suffering from swine erysipelas there is an increased heat production, and that this is due entirely to an increased destruction of proteid.

The following table of the results obtained by experiment upon three starving rabbits shows very well also how strikingly the destruction falls upon the proteids (Table XXX.).

May's next experiments are of the greatest interest to clinical physicians. He gave a starving rabbit a known quantity of grape sugar and made—both before and after the administration of the grape sugar—observations similar to those I have just described. After the observations the animal was immediately killed, and the glycogen in the body and the grape sugar in the urine, alimentary canal, and fæces were estimated, and from the figures obtained May was able to learn how much had been used in the body. The following table shows very well how the administration of sugar saves the destruction of albumin and fat which goes on in starvation (Table XXXI.).

TABLE XXXI.

Experimental medicine here shows strikingly why it is, as clinical medicine has found by experience, that milk and farinaceous diet is best for fever, and, further, as all May's experiments show conclusively that in starving rabbits suffering from swine erysipelas the heat production is increased, and that this increased production is due entirely to a greatly increased destruction of proteid, we are probably correct in concluding that in most fevers the greater part of any increased production of heat is due to an increased destruction of proteid rather than to an increased destruction of fats. It is true that May has not been able to allow for any energy which, resulting from the breaking down of tissue, manifested itself as mechanical work; but the increase of proteid destruction he found was so great that even if the fevered starving rabbit did a little more mechanical work than it did before the fever was induced the increased energy taking this form can have been only a small proportion of the whole energy resulting from the increased destruction of proteids. It is almost impossible to make any such observations on man, but some attempts have been made to find out whether in man the amount of CO_2 exhaled is increased during fever. Many more observations will have to be made on different fevers before the results can be accepted as final, but as far as they go they show that in man the amount of CO_2 excreted during fever is not increased. I will quote the results of two observers. Loewy[5] gives the following table of observations made on a case of typhoid fever (Table XXXIII.). It is noteworthy that not only is there no increase in the output of CO_2, but also that the respiratory quotient is low for man, whose normal is 0·8 or rather over this, although, according to May, the balance of evidence is that in fever it is unaltered.

Kraus[6] has also made a number of observations. He comes to the following conclusions: (1) That fever is possible when the oxidation processes (measured by determining the gaseous exchange) are not perceptibly increased,

[5] Virchow's Archiv, Band cxxvi., S. 218.
[6] Zeitschrift für Klinische Medicin, Band xviii., S. 160.

Digitized by Google

and this even during a long period in which the patient wastes; and (2) that the metabolic processes of fever do not markedly influence the respiratory quotient, which depends entirely on the condition of the patient. I ought to add that Zuntz, in a communication made to the Berlin Physiological Society, showed that different men under the same conditions varied very much in the amount of oxygen inhaled and the amount of CO_2 exhaled. Loewy and Kraus were, however, aware of this.

My work in this direction has been slight, for the only experiments I have done relate to the gaseous exchange of rabbits in which pyrexia had been induced by cerebral lesions and that of hybernating dormice. Mr. Hopkins and I investigated the question of whether the output of CO_2 and and H_2O from the lungs was increased when pyrexia was induced by cerebral lesions. We used the differential calorimeter I have already described. The animal was shut in one chamber, no hydrogen was lit in the other chamber, but it was closed and an equal amount of air was drawn through each chamber. The outcoming air from each was passed through a pumice and sulphuric acid tube to absorb the water, then through a U tube containing pumice soaked in caustic potash, and then through two U tubes each containing dry caustic potash. The sulphuric acid tube was weighed before an experiment, and each set of three caustic potash tubes was also weighed, and the tubes were then again weighed after an experiment the duration of which was

usually an hour. Of course, the sulphuric acid tube and caustic potash tubes on the animal side gained more than those on the other side, for these only showed the H_2O and CO_2 in the air drawn through, while those on the animal side showed this, and in addition the H_2O and CO_2 exhaled by the animal in one hour and taken up in the air current passing through the chamber. By subtraction we found how much H_2O and CO_2 were produced by the animal. The following table (Table XXXIV.) shows the results of four experiments on two rabbits.

It will be seen that the excretion of CO_2 was not in Rabbit A strikingly increased by the pyrexia due to the cerebral lesion, for although after both operations it was a little higher than immediately before, yet after neither was it so high as on two days before any operation. In Rabbit B there does appear to be a slight increase after each operation, but I think you will agree with me that the variations in both animals are so slight and so well within the normal variations that we may conclude that damage to the corpus striatum does not increase the output of CO_2, and in this respect the pyrexia which follows it is similar to the pyrexia which accompanies those fevers in which the excretion of CO_2 has been investigated. Inspection of the figures also shows that the pyrexia caused no constant alteration in the amount of aqueous vapour exhaled. It will be noticed also that it is impossible to trace any relationship between the CO_2 and H_2O in the air and that exhaled by the animal. I need hardly add that the position of the lesion in the brain was always confirmed by a post-mortem examination.

Dr. Pembrey and I have performed a number of experiments upon hybernating dormice.[7] When these creatures are hybernating their temperature is very low, the rectal temperature usually being about 9° or 10° C.; if they are brought out of a cold into a warm atmosphere their temperature slowly mounts at about the same rate as that of an equal weight of water (for their specific heat is very little less than that of water) until it reaches about 16° C., when it suddenly mounts many degrees in a few minutes to between 33° and 36° C.; at the same time the sleepy animal becomes active and runs about. The following table shows this rise (Table XXXV.). And it also shows that mere lowness of external temperature will not cause the animal to sleep or its temperature to fall. This will only happen when lowness of external temperature causes the creature to become inactive. This fact is very well shown in Table XXXVI.

TABLE XXXVI.—*Dec. 29th, 1895: Female Dormouse.*

Our observations brought out the interesting fact that this characteristic sudden rise of the animal's temperature was always associated with an equally sudden increase in the output of carbonic acid. The animal was placed in a chamber through which air was drawn, and the temperature of the air in the chamber was varied by alterations in the temperature of a water bath. As the air left the chamber the CO_2 in it was determined, a separate determination being made for each variation in the temperature of the air in the chamber. The following table (Table XXXVII.) shows very well this great increase in the output of CO_2; and the next table shows that, like the temperature, the output of CO_2 depends, not upon the external temperature, but upon the activity of the animal (see Table XXXVIII).

[7] Journal of Physiology, vol. xix., Nos. 5 and 6.

* The dormouse was coiled up and fast asleep at the end of the experiment.

We learn, therefore, that the rise of temperature which occurs when hybernating dormice become active is unlike the rise of temperature which occurs when a rabbit is afflicted with swine erysipelas or has its temperature raised by damage to the corpus striatum, for it is accompanied by an enormous increase in the output of carbonic acid. This goes to show what is probably true—namely, that the metabolic processes of the pyrexia due to cerebral lesions and of that due to fever are quite different from those of health, and not merely an exaggeration of these.

I think now we have come to the end of our discussion of the problem of the variations in the production and loss of heat in pyrexia, and the three great main conclusions to which we seem to have come are:—1. In man at least pyrexia is not produced by the same method in all fevers; sometimes the rise of temperature is due to an increased production of heat, and sometimes to a diminution of the loss. 2. In the present state of our knowledge animal calorimetry is very difficult, and the results obtained from calorimeters must be received very guardedly, especially when they are applied to man. 3. In some forms of pyrexia in which the production of heat is increased the metabolism leading to this takes place in the proteid tissues of the body, and probably the metabolic processes concerned in a pathological rise of temperature are different from those of health.

A very difficult problem which has been much occupying the minds of the profession lately has been that of why almost all micro-organisms which are harmful to the body raise its temperature, and the suggestion has been made that the rise of temperature is a defensive mechanism, or, in other words, pyrexia is, like phagocytosis or chemiotaxis, in some way harmful to the fever-producing micro-organisms, or

Digitized by Google

their toxins. Of course, it does not follow from this view that the higher the temperature of the body the better the prognosis, for the higher temperature might be taken to indicate that the dose of infection was very severe, and that therefore the body did all it could to resist the invasion, nor, on the other hand, would it follow that if the temperature did not rise much the dose of infection was slight, for it might be that the body was feeble and had but little power of raising its temperature and therefore defending itself. We see, therefore, that clinical observation can hardly settle the point, but in passing I may mention that I have seen a severe case of typhoid fever in which during the second week of the illness the temperature was very irregular; the patient, however, always felt better and had a better pulse when her temperature was high than when it was low.

A few years ago much was hoped from the antipyretic drugs—antipyrin, acetanilide, and phenacetin; and if it could have been shown that they distinctly improved the condition of the fevered patient it would have been a strong argument against the view that pyrexia is a defensive mechanism. The reverse, however, is the case, for they are not now often employed as antipyretics, and in a discussion on pyrexia and its treatment which took place at the Bristol meeting of the British Medical Association held in 1894, speaker after speaker got up and said that, as a general rule, it did more harm than good to treat the pyrexia of fever.

Some few fevers are treated by agents which lower the temperature, but these very fevers are instances of the exception proving the rule. Ague is treated by quinine, the temperature falls and the patient is better. This, however, is not because the quinine is an antipyretic, but because it is a poison to the plasmodium malariæ; the patient's temperature falls because the pyrexial agent is destroyed. The same is true of syphilis. If a patient is suffering from syphilitic fever his temperature falls when he takes mercury, not because mercury is an antipyretic, but because the cause of the pyrexia is destroyed. Again, it is almost certain that any benefit that follows in rheumatic fever from the administration of salicylates is not due to their antipyretic action, but because they are specifics for rheumatic fever, for other antipyretics are not equally efficacious, and salicylates benefit other symptoms than the temperature—viz., the pain. It is generally believed, and in all probability correctly, that many cases of typhoid fever are benefited by cold sponging or by a cool bath. Many have hastily concluded that the bath does good because it lowers the temperature. But this is probably incorrect. In the first place we must remember that the cold sponging or bath does more than lower the temperature; it diminishes the delirium, the tremor, and the prostration. In any of these ways it would do good. But, further, Roque and Weil claim to have shown that "in typhoid fever left to itself the toxic products manufactured by the bacillus and organism are eliminated in part during the illness. The urotoxic coefficient is double the normal, but this elimination is incomplete and is only completed during convalescence, for the hypertoxicity continues for four or five weeks after the cessation of the fever. In typhoid fever treated by cold baths the elimination of toxic products is enormous during the illness. The urotoxic coefficient is five or six times the normal. The hypertoxicity diminishes as the general symptoms mend and as the temperature falls, so that when the period of pyrexia and convalescence sets in the elimination of toxins has ceased." So we learn that it is by no means certain that in typhoid fever the benefit of cold baths is due to their antipyretic influence, and we see that clinical medicine affords no evidence that antipyretics are useful in fever.

I had hoped to be able to lay before you some original observations bearing on the question of whether or not pyrexia is a protective mechanism, but, unfortunately, I have not had time to carry them out, and therefore I must content myself with giving you briefly those of others. The best collection of the literature of this subject is given by Max Muller,[8] and many of the following references are quoted from him. Heydenreich[9] found that the spirillum of relapsing fever lost its mobility quicker at 40° C. than at 37° C., while at from 15° to 22° C. it retained it a long time. Then in 1880 Pasteur[10] made the observation that fowls which were ordinarily refractive against anthrax bacilli succumbed to them if their temperature had been artificially lowered by their being cooled, and in the same publication next year he said he had found that the virulence of anthrax bacilli is diminished by a temperature of from 42° to 45° C. Wagner[11] infected fowls with anthrax bacilli and spores, and kept down the temperature of some of them by partially immersing their bodies in water; these succumbed, but others left at the ordinary temperature did not. He also infected a series of eleven in whom the temperature was kept down by antipyrin; of these eleven six were taken ill; and of these six five died. This, he thought, was due to a lowering of the temperature by antipyrin. Rovighi, in a paper abstracted in volume vii. of the same *Centralblatt*, gives an account of how he infected three series of rabbits with saliva; one lot were placed in an incubator the temperature of which varied from 37° to 42°, another lot were left at the ordinary temperature, and the third lot were artificially cooled. He found the mortality to be highest among those artificially cooled and least among those artificially warmed; and in the same periodical for the year 1891 it will be found to be stated that Walther observed that after infecting rabbits with the pneumococcus those placed in a warm oven lived longer than those placed at the ordinary temperature of the room. Koch found that if tubercle bacilli were kept at a temperature of 42° C. for three weeks their development was much hindered, while the best temperature for their development was from 37° to 38° C. We thus see that this bacillus, the scourge of the human race, flourishes best at the internal temperature of man, and it is quite possible that if a phthisical patient's temperature could be safely kept at 108° F. for a month he might be cured. Fränkel[12] finds that the pneumococcus named after him loses its influence on rabbits in twenty-four hours if they are kept at a temperature of 42° C. Both Bumm and Finger have observed that the temperature at which the gonococcus flourishes best is between 33° and 37° C., and that higher temperatures stop its development. Max Muller came to the conclusion that the higher the temperature the less rapidly typhus bacilli multiplied. Welender and Berlien[13] have been treating soft sores by means of a thermostat, an instrument which keeps the sore at a temperature of 41° C., and they claim excellent results for this treatment. Filehne, at a meeting of the Physiological Society held at Oxford on August 11th, 1894, gave an account of some experiments in which he infected rabbits with erysipelas and studied the changes at the seat of infection, the ear. In animals kept in a warm chamber the reaction in the ear was slight, and attained its height in two days and the animal was soon well. In animals kept at the ordinary temperature the reaction was much more severe, and lasted ten or eleven days. In animals kept in a cool chamber nothing happened so long as they remained there, but as soon as they were taken out and left at the temperature of the room they had a very severe attack of erysipelas.

Loewy and Richter[14] caused a rise of temperature in rabbits by puncture of their corpora striata; they then infected them with the bacilli of diphtheria, fowl cholera, swine erysipelas, and pneumonia. They came to the following conclusions: (1) that with very large fatal doses the animals whose corpus striatum was punctured lived longer than the control animals; (2) if the animals whose corpus striatum was punctured had a dose two or three times as large as that necessary to kill an ordinary animal they recovered; and (3) when a local injection of swine erysipelas was made into a rabbit's ear the local reaction was most marked in those animals in whom the corpus striatum had been punctured, but they invariably got quite well.

I quite admit that all these observations do not prove that pyrexia is a protective mechanism, but they certainly suggest that it is, and many who have thought about the subject have given their adhesion to this view; such, for instance, are Roy,[15] Cantani,[16] and Sanarelli.[17]

It struck me some time ago that if pyrexia is a protective mechanism it might be a good thing to administer to fevered patients drugs that would raise their temperature, if before doing this it could be shown by laboratory experiments that such drugs have the power of diminishing the severity of fevers. There are many pyretic drugs. The

temperature may rise to 104° F. as a result of belladonna poisoning. In animals, at least, large doses of cocaine will cause a rise of temperature. It is said the best dose for producing this effect is a subcutaneous injection about eight milligrammes per kilogramme of the animal, the dose to be frequently repeated. Strychnine and caffeine, too, will both raise the temperature a little. But by far the most important drug for raising the bodily temperature in β-tetrahydronaphthylamine. Some remarkable experiments concerning this drug are given by Stern.[18] For instance, he took a rabbit weighing 1600 grammes, the temperature of which was 40° C., and at 10.42 A.M. injected subcutaneously 0·075 grammes of β-tetrahydronaphthylamine. The temperature was taken every few minutes afterwards with the following results:—At 10.55 A.M. the temperature was 40° C.; at 11.0 A.M. it was 40·2°; at 11.8 A.M. it was 40·9°; at 11.20 A.M. it was 41·4°; at 11.40 A.M. it was 43·0°; at 11.52 A.M. it was 44·5°; and at 12.2 P.M. the rabbit died. So that the drug actually raised the temperature 4·5° C. in an hour. By giving a smaller dose of the drug he was able to obtain a considerable rise of temperature without killing the animal.

Such a remarkable drug appeared to me to be worthy of further investigation, and Dr. J. Fawcett agreeing with me we made some experiments. We employed a 3 per cent. aqueous solution and always gave it subcutaneously. We performed several experiments; the following are the details of one.

The rabbit weighed 2400 grammes. At 1.30 P.M. the rectal temperature before injection was 38·7° C.; at 1.35 P.M. 3 c.c. of solution were injected; at 1.55 P.M. the temperature had risen to 39 3°; at 2.10 P.M. it was 40·5°; at 3.5 P.M. it was 41·5°; at 4 P.M. it reached 41·9°; and from 4.30 to 7 P.M. it gradually fell to 39·3°, and the following table (Table XXXIX.) shows the results of all our experiments.

TABLE XXXIX.—*Showing the result of injecting a 3 per cent. solution of β-tetrahydronaphthylamine subcutaneously in five rabbits.*

Number of experiment.	Weight of rabbit in grammes	Dose injected.	Time taken to attain maximum temperature.	Temperature at beginning in degrees F.	Temperature at end in degrees F.	Rise in degrees F.	Rise in degrees C.	Remarks.
1.	2400	3 c.c.	3 hrs.	101·6	107 4	5·8	3·2	—
2.	2050	3 c.c.	1¾ hrs.	102·7	112 6	9.9	5·5	This animal died; greatest rise.
3.	3570	4 c.c	2 hrs.	103 1	106·8	3·7	2·1	—
4.	2200	3 c.c.	2¼ hrs.	101 4	104·3	2·9	1·6	Least rise.
5.	2200	3·5 c.c.	4 hrs.	101·8	105·0	3·2	2·2	—

It will be seen that in one animal a rise of 5·5° C. took place. This died, but all the others recovered, and in one of them there was a rise of as much as 3·2° C. In all five experiments the pulse and respiration were enormously increased in rapidity, often both were so quick that they were quite uncountable. We never observed any of the variations in the size of the pupil or the vessels of the eye that Stern mentions. As animals which, like rabbits, do not perspire much must lose most of the heat they part with by the lungs, the rise of temperature produced by β-tetrahydronaphthylamine cannot have been due to a diminution of the loss of heat. Indeed, judging by the rapidity of respiration, this must have been much more rapid than usual, and probably the creature was by increasing its heat loss struggling against the rise of temperature produced by the drug. The animals for an hour or two after the drug was injected were usually rather restless, frequently shifting their position and turning round, but they never ran about or made any prolonged severe muscular movement. This restlessness was always followed by marked loss of muscular power, but nevertheless the temperature continued to rise. The only animal that had convulsions was the one that died, and they did not appear until shortly before death. These facts seem to me to be strongly in favour of the view that the drug has in some way greatly increased the production of heat, and that this increased production is not due to muscular movement, for the rise is altogether too great and too rapid for it to be caused even in large part by the increased muscular movement due to the greater rapidity of the respiration and pulse. In support of this view I may mention that Stern was also of opinion that the muscular movements were not sufficient to explain the rise of temperature, for in his experiments this sometimes occurred in animals which were quiet without any drug being given to keep them quiet, and also in those which were kept quiet by morphia. Further, the rise of temperature that is seen in animals convulsed with strychnine is never nearly so great as that produced by β-tetrahydronaphthylamine, although rabbits under the influence of this drug never show muscular contractions comparable to those produced by strychnine. Then, too, some experiments performed by Mosso go to show that even the comparatively slight rise of temperature in strychnine poisoning is not due solely to muscular contractions. I cannot help thinking, therefore, that we have in β-tetrahydronaphthylamine a drug which stimulates the thermogenetic without exciting the motor function of muscle, and that therefore we see—as we have already seen in the patients afflicted with hemiplegia—that the two functions are distinct.

I have already pointed out in these lectures that damage to the corpus striatum produces a considerable rise of temperature. The rise produced by β-tetrahydronaphthylamine so resembles in extent and rapidity that caused by these injuries that it is at least likely that the drug acts on the muscles through the central nervous system. Dr. Fawcett and I tried to find out whether this was so, but all the experiments we could devise necessitated fixing the animal down and performing artificial respiration, and, as I have already pointed out, this interferes so much with the animal's temperature that we were unable to obtain any satisfactory answer to the question we attempted to solve.

I have not yet had time to see whether the administration of this drug increases the resistance to any febrile diseases, but it is clear that even if it does it will have to be given very cautiously to man on account of its marked effect on the heart.

The only duty that now remains to me is to thank you for having listened to these lectures, and to express my regret that they should have been so imperfect and fragmentary. This is, for the most part, my fault, but it is also due to the difficulties of the subject. I have not referred to the work of many to whom reference should be made were I writing a full account of pyrexia; this is because I believed the founder's wish to be that lecturers should relate what they themselves had done and thought rather than that they should give a condensed account of what others had done and thought.

A SECOND SERIES OF FOURTEEN CASES OF EXCISION OF THE RECTUM.

BY F. T. PAUL, F.R.C.S. ENG.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

A PAPER on the first series of fourteen cases was read at a meeting of the Liverpool Medical Institution two years ago.[1] They were all malignant; thirteen were carcinoma and one was sarcoma. The present series is comprised of two cases of syphilitic stricture, two of villous tumour, and ten of carcinoma.

The minute structure.—I make it a rule to examine with the microscope all tumours removed, and it is strange how frequently one finds deviations from the normal type of growth, or something altogether unexpected. The first example of this in this series was Case 17. The patient was a spare, anæmic woman, aged fifty-six years, who had five years' history of constant desire to defæcate, with passage of mucus and blood. On examining her a very large mass of what was supposed to be soft fungating carcinoma was felt two and a half inches from the anus. It surrounded the

Digitized by Google

bowel and extended up out of reach. Six inches of rectum were removed by the "sacral route." She made a slow but good recovery, and is still well. I only discovered something unusual about this tumour when, on putting a piece into the fixing solution, villous fringes floated out in the fluid. Further investigation showed that the whole of this mass of growth, which involved more than three inches of the whole circumference of the bowel, and was upwards of an inch thick, consisted of branching villi covered with a single layer of long columnar cells having small nuclei placed near their bases. Villous tumours of the rectum are supposed to be rare, and I have never seen a report of one so extensive as this. The patient was operated on in July, 1895, and she was still quite sound in April, 1897. The other case of villous tumour was much smaller and was recognised as a probably innocent growth before operation. It occurred in Case 25, in a woman also aged fifty-six years, and occupied an oval patch on the anterior wall of the rectum about 2 in. by 1 in., and was situated two inches above the anus. It was excised with the whole thickness of the bowel through a posterior median incision. The parts were sutured, and a normal rectum resulted. She has left her old address, and I cannot find her; but in such a case recurrence is practically out of the question. The microscopical structure is like the last—essentially innocent.

The next two cases worthy of attention on account of their pathological interest are those of a man aged twenty-seven years, and a woman aged forty-six years (Cases 23 and 26). Both were admitted with malignant stricture, and both had a history of the previous removal of a polypus—the man in New York seven months previously, and the woman in London in St. Bartholomew's Hospital by Mr. Willett three years previously. The polypus in the man's case may have been malignant, for the tumour had the usual characteristics of colloid cancer; but that in the case of the woman was probably, nay, almost certainly, innocent, for the entire piece that I took was pure villous tumour, in which the other coats of the bowel, including the sub-mucous coat, were absolutely normal. Another part, however, examined by Mr. Robert Bickersteth, was cancerous. Of course, we knew the tumour was in part malignant, for there were cancerous glands in the meso-rectum. No doubt the part I examined was some of the original disease—a simple villous tumour. But the original growth in time became malignant, and thus furnishes another example to those who doubt that innocent tumours may become malignant. Another point of interest in the man's case was that he had a malignant gland (of the same character) in the left groin. This is the only time that I have seen cancer in a gland in the groin secondary to a growth placed well within the rectum. During my absence last year another case of villous tumour becoming malignant was admitted. It consisted of three polypoid masses, one of which has the appearance of villous tumour, but the others of cylindrical-celled carcinoma. It was very successfully excised through a posterior median incision by Mr. Robert Bickersteth. The man left with a normal rectum and has remained well since. Thus no less than four (possibly five) cases of villous tumour of the rectum have been met with in one year, though only two retained their innocent features at the time of examination. I can quite understand that those who have not the opportunity of seeing these specimens may feel a little sceptical at such an extraordinary percentage, but in about fifty cases of tumour of the rectum which I have examined microscopically these are the only examples of villous tumour met with.

In the first series of cases I called attention to one of squamous-celled epithelioma, which started in the mucous membrane of the bowel (Case 8). In this series there is another (Case 21). It occurred in a woman aged forty-seven years, and caused a tight stricture one-and-a-half inches above the anus. It infiltrated the vagina, but evidently did not originate there, as the vaginal mucous membrane was intact. Such abnormal forms of carcinoma probably grow in "rests" or in tracts of tissue such as give rise to rectal dermoids. Finally, in this connexion, the evidence is again in favour of colloid being decidedly more malignant than cylindrical-celled carcinoma. I mention this, as the contrary opinion seems to prevail.

The operation.—The methods used may be arranged as follows: (1) perineal incision, which suffices for the removal of about three inches of bowel—more in the female; (2) the same, combined with excision of the posterior wall of the vagina, which gives a great deal of room—the vagino-perineal operation; (3) posterior median proctotomy for the removal of small growths with subsequent suture; and (4) the sacral operation of Kraske. In none of these cases has the upper part of the rectum been removed by abdominal section.

Partial excision of the rectum through the perineum is a very successful operation. It is generally in these cases, in which the growth is small and situated near the anus, that we may hope for a long immunity. Growths higher up are longer in attracting the patient's attention, and the glands of the meso-rectum are often involved before they are recognised and sent for operation. If the patient is able to bear the complete operation, it is always better to excise the entire circumference of the bowel in all cases in which the removal is too extensive to permit restoration of its calibre by suture. In those cases in which I have removed a growth from the posterior wall and left part of the anterior wall and anus, the discomfort from mucous discharge and prolapse has been considerable, and I have found it desirable to subsequently cut away all exposed mucous membrane. In fact, the subsequent discomfort from these slight operations has generally far exceeded that of the removal of six or seven inches of bowel.

The vagino-perineal operation is a good one, but it is, of course, essential to restore the vagina and perineum. I once saw a patient upon whom this operation had been performed without restoration, and the result was deplorable, for the whole of the pelvic organs prolapsed from want of support. When the diseased parts have been excised the stump of the rectum is brought out at the posterior end of the wound attached to a glass tube; the remains of the elastic wall of the vagina are sutured in front, and deep silver sutures are passed between the two and a very long perineum procured. Generally the anatomical result is excellent, and as a corroborative detail it may be mentioned that two of my younger patients married after this operation, but, perhaps fortunately, did not become pregnant.

The posterior median proctotomy for the removal of small growths with subsequent restoration of the bowel is perhaps the most interesting operation. A long backward incision is made, carried up over the sacrum if the tumour is in the middle third, and the bone is cut across and turned as a flap to the left side. The rectum is then opened in the middle line, and the disease examined with the finger. If it is a short stricture the entire circumference is excised; if an oval patch then only the affected part. In either case restoration is best effected by sutures and not by Murphy's button. Having sewn up the wound made in the bowel for the removal of the growth the posterior lineal incision is closed, the sacral flap restored, and the anus forcibly dilated to paralyse the sphincter. In some cases the result of this operation is nearly perfect.

The sacral operation of Kraske is, of course, the most serious. The incision is made as in the last case, the coccyx, or coccyx and lower part of the sacrum, being cut across and turned to the left. It is important to retain these bones, as when their support is lost the bowel may prolapse badly unless the special truss recommended in my former paper is worn. Having exposed the bowel, if the growth is high up it may be cut across below, and the anus left intact; if not, dissect it entirely up from below. There is no value in the lower piece of bowel, only its removal makes a larger wound. Next, with constant use of compression forceps and aneurysm needle before the knife or scissors, clear the bowel until the meso-rectum is cut away and the peritoneum freely opened; then draw down as much as is necessary to insert a glass tube above the growth, ligature it in, and cut off the latter. Enough bowel must be drawn down to allow the end to be brought out of the wound without tension. The sacral flap is then restored, the bowel connected to the skin with sutures, and the rest of the large wound in front packed with cyanide gauze.

I have tried various ingenious methods, including Murphy's button, to approximate the upper and lower ends after extensive removal, and I am now persuaded that any such attempt is bad practice when the excision exceeds two, or at most three, inches of bowel. The healing is longer and more dangerous and the result little, if any, better. It would occupy too much space to go into the reasons, but I have tried approximation after extensive removal several times, and I regard it as a failure. It is certainly more dangerous than the glass tube method I formerly recommended, and to which I have decided to return. On the other hand, the use of a sacral flap in place of cutting away

Digitized by Google

the bones is a distinct improvement, and I believe at the present time only one patient is wearing a truss, and that is for the partial perineal operation. All the Kraske cases describe themselves as having little or no loss of control over their bowels. In fact, they are more inclined to stricture than a patulous anus with prolapse.

Results.—The anatomical results have been referred to in describing the operations. The best result is obtained when a small growth or short segment has been removed and the parts have been satisfactorily united by suture. The next best is after the complete removal of the lower end of the bowel, whether by the perineal, vagino-perineal, or sacral operations; it does not matter how much is removed so that a clean end is brought out and the natural support of bones or perineum is made good. The worst anatomical results follow when a lot of exposed mucous membrane is left with a long slit-like anus, or when the support of the perineum or sacrum and coccyx is wanting.

Clinically there are many circumstances which influence the success of the operation, apart from the physical powers of the patient and the skill of the surgeon. The chief of these are: 1. Early recognition of the disease.—This means that either it is low down or has rapidly formed a ring stricture. In the majority of cases the early symptoms are slight, and when the patient seeks advice the tumour is already large. 2. The nature of the growth.—In innocent tumours the result should of course be cure, though in operating through the anus this does not appear to be the case with villous tumour. A villous tumour is generally a sufficiently serious affection to call for posterior median proctotomy. Of malignant tumours the usual cylindrical-celled carcinoma of the part offers the best prospect; squamous-celled epithelioma perhaps the next best; colloid and sarcoma the worst. 3. Involvement of glands.—Wherever I find malignant glands in the meso-rectum I always regard the case as certain to have a recurrence. Occasionally the glands may be recognised before operation, but usually they are concealed by the tumour. 4. Age.—

TABLE OF TWENTY-EIGHT CASES OF EXCISION OF THE RECTUM

Case.	Date.	Sex.	Age.	Site of tumour.	Operation.	Amount removed	Result.	Died later.	Still living.	Remarks.*
1	1881	M.	47	Lower third of rectum, small.	Through perineum.	2¼ in.	Recovered.	—	10 or more years.	Shown at Liverpool Medical Institution, 1885. Left in good health for America, 1891.
2	1888	F.	56	Lower third, small.	Through perineum.	2½ in.	Recovered	2½ years.	—	Had stricture of rectum.
3	1890	F.	37	Middle third; sarcoma.	Kraske (tube).	7 in.	Recovered.	One year.	—	Died of recurrence in internal organs and skin at distant parts.
4	1890	M.	46	Middle and lower thirds.	Kraske (tube).	6½ in.	Recovered.	Ten months	—	Previous colotomy. A small piece of growth left in ureter.
5	1891	M.	41	Middle and lower thirds.	Kraske (tube).	7 in.	Recovered.	4 years.	—	No recurrence for three years. At work all the time.
6	1891	F.	55	Middle and lower thirds.	Kraske (tube).	5 in.	Died.	—	—	Died on the eleventh day. Exhaustion.
7	1892	M.	56	Middle third.	Kraske (tube).	8 in.	Recovered.	2½ years.	—	At work for two years as agent.
8	1892	F.	29	Lower third.	Vagino-perineal incision.	4 in.	Recovered.	2½ years.	—	Removed part of vagina. Very well for some time. Got married.
9	1893	M.	59	Lower third, small.	Through perineum.	3 in.	Recovered.	—	4 years.	Working all the time. Very well.
10	1893	M.	64	Middle third, small.	Kraske (approximation).	2 in.	Recovered	Lost sight of	after 2 years.	Perfectly normal rectum.
11	1893	F.	42	Lower third.	Vagino-perineal incision.	4 in.	Recovered.	10 months.	—	Rapid recurrence owing to infected lymphatics. Part of vagina removed.
12	1893	M.	56	Lower third.	Kraske (approximation).	4 in.	Recovered.	—	3½ years.	Normal rectum.
13	1893	M.	64	Middle and lower thirds.	Kraske (approximation).	4½ in.	Recovered.	2½ years.	—	Anus incomplete behind.
14	1894	M.	60	Middle third.	Kraske (tube).	4 in.	Died.	—	—	Patient greatly reduced by previous complete obstruction and colotomy.
15	1895	M.	60	Lower third.	Through perineum.	4 in.	Recovered.	1 year.	—	Adherent to bladder.
16	1895	M.	64	Lower and middle thirds.	Kraske (approximation)	7½ in.	Recovered.	6 months.	—	Had malignant glands.
17	1895	F.	55	Middle third (villous).	Kraske (tube)	6 in.	Recovered.	—	20 months.	Good anus.
18	1895	F.	23	Lower and middle thirds.	Kraske (tube).	4½ in.	Recovered.	?	—	Very well for some time. Married. Recurrence after one and a half years. Not seen lately.
19	1895	F.	34	Entire rectum (syphilitic).	Kraske (tube).	5 in.	Recovered.	—	17 months.	Much better.
20	1896	F.	64	Lower third.	Through perineum.	3 × 2 in.	Recovered.	—	13 months.	No recurrence.
21	1896	F.	47	Lower third.	Vagino-perineal.	3 in.	Recovered.	—	12 months.	No recurrence; good anus.
22	1896	F.	25	Lower third (syphilitic).	Through dilated rectum.	½ in.	Recovered	—	11 months.	Diaphragm stricture; perfect restoration.
23	1896	M.	27	Middle and lower thirds.	Kraske (tube).	4 in.	Recovered.	—	10 months.	Glands infected.
24	1896	F.	57	Middle and lower thirds.	Vagino-perineal.	4½ in.	Recovered.	—	10 months.	Colloid growth; glands.
25	1896	F.	56	Middle third (villous).	Post. median proctotomy.	2 × 1½ in.	Recovered.	—	8 months.	Normal rectum.
26	1896	F.	46	Middle and lower thirds.	Kraske (approximation)	4 in.	Recovered.	—	6 months.	Cancer following villous tumour.
27	1896	M.	63	Middle third, extensive.	Kraske (approximation).	3½ in.	Died.	—	—	Localised peritonitis; shock.
28	1896	F.	34	Lower third.	Vagino perineal.	3½ in.	Died.	—	—	Cancer very foul. Exhausted patient. Shock and septic wound.

* The tumours were malignant where not otherwise mentioned.

Digitized by Google

The younger the patient the less the chance of permanent cure. I have now seen quite a dozen cases under twenty-five years. The rectum is, I think, the earliest of all sites for true carcinoma, though a majority of the patients are between fifty and seventy years of age.

In regard to the survival of my cases after the operation I can speak with some degree of certainty, as I have taken considerable pains to keep them under observation. Of the first series of fourteen all were cases of malignant disease. One was certainly cured; several survived for from one to four years, and I predicted that one if not two more would prove to be cured. I am glad to report that so far this prediction seems likely to be fulfilled. One is a patient of Dr. Peirce, of Hoylake, and I hear that he is sound and well, working every day on his farm at the age of sixty-three years. The other is a patient of Dr. Gwynn, of Whitchurch, and he writes me that this man is "so well that he has not seen him for months," and having now re-examined him reports that "there is no appearance of a return of the disease, and the control over the parts is good." In the former the operation was done rather more, and in the latter rather less, than four years ago. Of the first fourteen cases of malignant disease, the last of which was operated on more than three years ago, I can now make the following definite report. Two died from the operation; three are cured; one was under observation for ten years and the other two for four years. One more I am almost certain is cured, but I lost sight of him after two years, when he was perfectly well. He lives in the heart of Wales, and all my letters come back without having reached him. The remaining eight averaged just two years of life after the operation, all of them dying from recurrence. In my judgment there are very few parts of the body where better results can be obtained when dealing with cancers of considerable dimensions.

In regard to the second series of fourteen cases four are non-malignant. They are all well and likely to remain so. Of the ten cancer cases two died from the operation, and two more have died since from recurrence, one at the end of twelve months and the other at the end of six months. This has been rather an unlucky series of cases, many of them having had enlarged glands in the meso-rectum at the time of the operation. I dare only predict that one may prove a cure—Case 20, a woman aged sixty-four years, who had a cylindrical-celled carcinoma 2½ in. by 1½ in. on the posterior wall of the rectum about two inches from the anus. In Case 21 I examined the patient in May, and she is quite free from recurrence twelve months after operation; but her tumour proved to be squamous-celled carcinoma, and I have less hope of cure in this form of growth. However, things may turn out better than I expect. Six of the ten operated on during the last two years are well and, so far as I can tell, without fresh growth. The case in which Mr. Robert Bickersteth operated for me, which is not included in the table, has probably a better prospect of permanent cure than any of the others.

Fatal cases.—The mortality is exactly the same for both series—namely, 14 per cent. In the first series the two deaths occurred in elderly patients and were the result of shock, one dying gradually on the eleventh day from exhaustion and the other rapidly soon after the operation. In the present series I had no death until the last two cases—the first in an old man, aged sixty-three years, who died on the sixteenth day from chronic septic poisoning, and in whom localised peritonitis was found. I blame the result here upon approximating the bowel after an extensive removal. The union was imperfect and the wound became septic before the peritoneum had healed. Had I brought the stump out and connected it with the glass tube the operation would have been shortened by perhaps half an hour and the wound would not have been contaminated with fæces until the peritoneum had closed. The second death occurred in a young woman with a remarkably foul cancer. It was so virulent that every little crack in the skin of my hands became poisoned, and I had five sores which refused to heal till I left home. No wonder that her wound was septic and that she, being in a very anæmic and exhausted condition at the time of the operation, gradually died on the twenty-fifth day. The peritoneum was not opened in her case.

Although the cancer cases are, on the whole, less favourable in this series than the last, I continue to thoroughly appreciate the value of the operation of excision of the rectum. In the less severe cases one has an excellent chance of obtaining a cure, and in many of the bad ones there is a considerable period of immunity during which life is by no means a burden to the majority.

The syphilitic cases.—Having included two cases in which I operated for syphilitic stricture, it is right that I should say a word respecting them. Case 22 offered such a tempting opportunity for a "radical" cure that I at once suggested that we should excise the stricture without attempting dilatation with bougies. She had a diaphragmatic stricture about an inch above the anus, and after dilating the latter I was able to draw it outside and excise it without the least difficulty. The wound was carefully sutured, it healed by first intention, and when examining her a month or two subsequently I could not detect the site of the operation. Case 19 was a very different business. Here we had an anæmic patient who had suffered for years from incurable syphilitic stricture. I had done what I could with bistoury and bougies, and it was her own desire that stronger measures should be taken. Under these circumstances, as life was really a burden to her I made the Kraske's incision and attempted to excise the whole rectum. But it was a more difficult and dangerous operation than I anticipated, owing to the dense adhesions contracted by the bowel with all neighbouring structures, and I found when I had got five inches freed that her condition was such as to make it imperative to conclude the operation at once. A glass tube was consequently ligatured in, the wound was packed with gauze, and the patient was sent back to the ward. Convalescence was slow, but in the end she recovered. There are still some two or three inches of strictured bowel, but it is not so narrow as that which was removed and yields to bougie treatment, which she is now carrying out herself. I have no reason to suppose that this patient is dissatisfied with the result of her operation, and she is certainly much better pleased in having the artificial anus near the old spot than she would be if it were in the groin, but knowing now myself the difficulties and dangers to be encountered in bad cases of syphilitic stricture I should in future have no hesitation in recommending colotomy when it was impossible to obtain relief by simpler measures. This, of course, does not apply to special cases like Case 22. Here no danger whatever is run, and there is no reason to object to excision if the surgeon thinks it to be the best method of relieving his patient.

Liverpool.

THE LOCALISING VALUE OF OPTIC NEURITIS IN INTRACRANIAL TUMOUR.

BY J. M. MARTIN, B.A., M.B., B.C. CANTAB.

DURING the last thirty years general opinion has wavered greatly as regards the certainty and frequency with which optic neuritis is produced by a growth within the cranium, and the greatest authorities from time to time have made diametrically opposite statements with regard to this condition. At various times it has been stated that optic neuritis has no localising value as regards the seat of disease, and at other times the directly contrary opinion has been put forward. Thus Dr. Hughlings Jackson in 1880 stated that "optic neuritis is of no value in localising disease in any part of the cerebrum or cerebellum," and Mr. Horsley now holds that optic neuritis is of distinct value in locating the position of the disease, more particularly as regards the side on which the disease is situated. But it is when we come to the question of unilateral optic neuritis that we find the greatest difference of opinion. For some observers state that in a case in which optic neuritis appears only in one eye, or appears in one eye before the other, or is more marked in one eye than in the other, the seat of lesion is on the opposite side of the brain; whereas others equally positively state that the lesion is on the same side as the eye in which the optic neuritis first appears or is more marked. It is as an attempt to try to arrive at the true facts of the case by examining rather a larger number of reports than has been presented before that I now bring forward the results of my analysis of 600 cases, which I have collected from various sources. Before I begin the discussion of the special subject

Digitized by Google

of this paper it will be of some value—if only to confirm the researches of former investigators—to give a general analysis of my series of cases and then consider the question of the localising value of optic neuritis. The result will not be so complete as I had hoped it would be, as in very few cases comparatively has it been noted in which eye the optic neuritis appeared first or was more marked.

It has always been stated that the male sex is more liable to intracranial growths than is the female sex. The numbers in my series are as follows :—

TABLE I.

Position of tumour.	Male.	Female.	Sex not stated.	Total.
Frontal	31	17	13	61
Temporo-sphenoidal	13	10	5	28
Motor area	77	22	22	121
Parieto-occipital	19	10	8	37
Multiple	18	9	1	28
Basal ganglia	20	12	4	36
Corpus callosum	7	5	1	13
Centrum ovale	19	10	1	30
Corpora quadrigemina	12	3	0	15
Pituitary	13	9	4	26
Crura	3	1	1	5
Pons and medulla	29	11	4	44
Cerebellum	82	34	22	138
General	10	7	2	19
Total	353	160	88	601

So that of 513 cases of intra-cranial tumour 68·8 per cent were males and 31·2 per cent. were females; that is, the male sex is more than twice as liable as the female sex to intra-cranial growth.

Having here given my first table it will perhaps be well at this point to define the regions I have adopted. Frontal—those tumours situated in front of the ascending frontal convolution externally, and as far back as the genu of the corpus callosum internally. Temporo-sphenoidal—those situated in the part of the cerebrum below the fissure of Sylvius and limited posteriorly by a line drawn from the posterior end of the fissure of Sylvius above to the lower end of the ex-occipital fissure below on the outer surface, and by the calcarine fissure on the mesial surface. Motor area—those situated in the precentral, post-central, and paracentral convolutions and their immediate neighbourhood. Parieto-occipital—those situated in or near the remaining cortex of the brain. As regards the remainder, all that need be said is that they affect only or chiefly the structures under the names of which they appear. Those included under "general" were either too diffuse to be put under any more definite heading or else their actual position was not stated in the report from which I obtained my abstract.

TABLE II.

Nature of tumour.	Tuberculous.	Sarcoma.	Glioma.	Glio-sarcoma.	Cystic.	Carcinoma.	Gumma.	Hydatids.	Other tumours.	Total.
Frontal	31	16^{3}	8	5^{2}	2^{2}	2	6^{2}	3	16^{1}	61^{11}
Temporo-sphenoidal	1	8^{2}	5	0	2	1	3	2^{1}	6^{4}	28^{7}
Motor area	8^{3}	29^{12}	13^{3}	6^{1}	5^{1}	3	13^{3}	3	40^{21}	120^{49}
Parieto-occipital	1	11^{3}	6	1	1^{1}	1	2	3	11	37^{3}
Multiple	8^{4}	6	2^{1}	0	1	1	4^{2}	2	4^{2}	28^{9}
Basal ganglia	7^{2}	3	7^{1}	5^{2}	1	0	0	1^{1}	12^{3}	36^{9}
Corpus callosum	0	4^{3}	0	2^{1}	0	0	0	0	7^{4}	13^{8}
Centrum ovale	2^{1}	6^{3}	3^{1}	1	3^{2}	0	1	3	11^{5}	30^{11}
Corpora quadrigemina	2	5	2	0	1	0	1	0	4	15
Pituitary	2^{1}	5^{1}	2^{1}	0	2	2^{2}	1	0	12^{3}	26^{8}
Crura	0	1	0	0	0	0	0	0	4	5
Pons and medulla	12^{7}	5^{1}	12^{2}	1	1	1	2^{1}	1^{1}	10^{3}	45^{14}
Cerebellum	25^{5}	20^{3}	21^{3}	9^{2}	25^{2}	0	3	3	32^{3}	138^{18}
General	1	7^{2}	1	0	0	0	0	0	10^{1}	19^{3}
Total	72^{36}	126^{32}	82^{15}	30^{8}	44^{8}	11^{2}	36^{8}	21^{3}	179^{49}	601^{151}

The nature of the growths in each position will be found in the next table (Table II.); the significance of the small figures in the top right-hand of some of the figures will be explained subsequently (see Table VI.). From this it will be seen that of the 442 named tumours 126 were sarcomata, 82 were gliomata, and 72 were tuberculous—a result which differs from Starr's[1] as below.

	Starr.	J. M. M.	
Sarcoma	22·6	28·5	percentages.
Glioma	17·2	18·5	
Tuberculous	36·4	16·3	

While I was abstracting my cases it seemed to me worth while to notice the chief position of the headache in each case where it was mentioned, as, so far as I am aware, there are no statistics on this point: but the result is only to confirm the prevailing idea that the position of the headache is of no value in determining the position of the tumour (see Table III.). The only points to which I will draw attention are the number of cases of tumour of the motor area and of the corpus callosum in which headache was stated to be absent, the frequency of occipital headache in cerebellar tumours, and of frontal headache in all kinds of tumours.

TABLE III.

Position of tumour.	Position of headache.								
	Stated to be absent.	Frontal.	Frontal and occipital.	Occipital.	Vertical.	Temporal.	Fronto-temporal.	Parietal.	Fronto-vertical.	Occipito-vertical.

Cerebellum	—	18	7	23	1	—	—	2	4	3
General	—	5	—	—	1	1	—	1	—	—

The results of my analysis of these 600 cases as regards the presence of optic neuritis are in accord with the generally accepted statements, but I have gone rather more into detail than has usually been the case; thus I have separated the cases in which optic neuritis was noticed into four groups, with the idea of seeing whether any new facts would be brought out; these groups are—(1) those cases in which the optic neuritis was stated to be unilateral; (2) those in which the optic neuritis was beginning late in the course of the disease; (3) those in which the optic neuritis was early and marked; and (4) those in which the optic neuritis went on to atrophy or in which atrophy was first noticed (see Table IV.). Before I go fully into the table I will draw attention to the comparatively small number of cases which go on to atrophy in the following groups:—(1) the pons and medulla; (2) the temporo-sphenoidal; (3) the motor area; (4) the corpus callosum; and (5) the corpora quadrigemina (here notice the large proportion of cases in which optic neuritis is found). The number of cases of tumour of the crura is too small for me to draw any general conclusion from them. Optic neuritis is constantly present in tumour of the corpora quadrigemina, so that in the absence of optic neuritis we can

[1] Nervous Diseases, edited by F. X. Dercum, p. 471.

Digitized by Google

exclude this position for the tumour. The cerebellum and parieto-occipital regions come second with optic neuritis in 39 per cent. of cases, but a marked difference is noticeable in the two groups when we come to Table IV., column iv., excluding optic atrophy; here the cerebellar region leads by 13 per cent. The only other special point to which I will draw attention is the comparatively small proportion of cases in which optic neuritis is found in tumours of the corpus callosum and of the pons and medulla—a fact which is still more marked when we exclude "atrophic" cases. If we exclude the eight cases of the pons series in which internal hydrocephalus was produced, and in every one

TABLE IV.—*General Table for Optic Neuritis.*

PERCENTAGES.—I., in which optic neuritis was present some time in the course of the disease. II., in which optic neuritis was late, absent, or unilateral. III., in which optic neuritis was present early in the disease. IV., in which optic neuritis was present, excluding atrophic cases.

of which optic neuritis was found, the figures will stand:—Cases, 36; no optic neuritis, 14; unilateral, 4; late, 6; marked, 9; and atrophy, 2 (special reasons), which will make the percentages as follows: Cases in which optic neuritis was present some time during the disease, 56; cases in which optic neuritis was present early in the disease, 26·4. Thus the absence of optic neuritis early in the disease is a characteristic of tumour of the pons. Before leaving this point I will arrange the groups in their order—(1) according to the percentage of optic neuritis (all cases); and (2) according to the percentage of cases in which optic neuritis is late, absent, or unilateral.

(1)	(2)
1. Corpora quadrigemina.	1. Cerebellum.
2. Crura.	2. Corpora quadrigemina.
3. Cerebellum. / Parieto-occipital.	3. Parieto-occipital.

9. Corpus callosum.	9. Motor area.
	10. Pons and medulla.
	11. Corpus callosum.

I come now to the table of the cases in which optic neuritis was unilateral or more marked on one side than on the other, and among them I have included three (motor area) which were clearly diagnosed at the National Hospital for the Paralysed and Epileptic, Queen-square, but which have not been operated on and have not reached a fatal termination (see Table V.).

TABLE V.—*Unilateral Neuritis.*

Tumour.	Optic neuritis more marked on the side of the lesion.	Optic neuritis more marked on the side opposite to the lesion.	Totals.
Frontal	8	2	10
Temporo-sphenoidal	4	0	4
Motor area	14	3	17
Parieto-occipital	2	4	6
Multiple	2	0	2
Basal ganglia	1	0	1
Centrum ovale	1	2	3
Corpora quadrigemina ...	1	0	1
Pituitary	0	1	1
Pons and medulla...	3	2	5
Cerebellum	3	1	4
General	0	1	1
Total	39	16	55

From this it will be seen that I have been able to collect only 55 cases useful for this purpose, but in future a much larger proportion will be available, as the amount of swelling of the papilla is being measured in each eye much more accurately than has been done in the past. Yet even here there are quite sufficient data to justify one in stating absolutely that the seat of lesion is probably on the side on which optic neuritis is more marked in the proportion of 71 to 29. If we take the first three groups in the table among which we have the largest number of cases the results are as follows: total on the side of the lesion, 26; on the side opposite to the lesion, 5; total, 31. The percentage in favour of the lesion being on the side of the optic neuritis is 84.

Turning now to the question of the effect of the nature of the tumour in producing optic neuritis, I have in Table II. (small figures above referred to) included the number of cases in which optic neuritis was absent or very slight in connexion with each kind of tumour in each region. The individual numbers are too small to give any satisfactory results, but on taking the totals the percentages are sufficiently striking to be worth noticing (see Table VI.).

TABLE VI.

—	No. of tumours.	Optic neuritis absent.	Percentage.
Tuberculous	72	26	36
Sarcomata	126	32	25
Gliomata	82	15	18
Glio-sarcomata ...	30	8	27
Cystic	44	8	18
Carcinoma	11	2	18
Gumma	36	8	22
Hydatids	21	3	14
Total ...	422	102	24

The conclusions then are: (1) that optic neuritis is most often absent if the tumour is tuberculous; and (2) that optic neuritis is most frequently present if the tumour is a glioma, is cystic, or is a hydatid.

The last set of statistics I have worked out is that in relation to strabismus in cases of intra-cranial tumour; there were only thirty cases in which I could get a clear idea of this condition from the reports; the result is as follows (see Table VII.). Hence in cases in which internal strabismus is noticed the tumour is generally on the same side.

Before bringing my paper to a close I will sum up the general results which I have obtained:—1. That 68·8 per cent. of all cases of intracranial tumour are among males. 2. That the most common form of intracranial growth is sarcoma; gliomata and tuberculous tumours are of about equal frequency, but less common than sarcomata. 3. That headache is more likely to be absent in cases of tumours of the motor area and of the corpus callosum than when the

Digitized by Google

tumour is situated elsewhere. 4. That the tumour is generally situated on the side on which internal strabismus is noted.

Has, then, optic neuritis any localising value in intracranial tumour? It has, yet only to a limited extent at present; but under the improved methods of examination now adopted it will be of more value in the future. Where a difference in the amount of the optic neuritis in each eye is noted it is more than twice as probable that the tumour is on the side of the more marked optic neuritis. Beyond this little can be said, but at the same time it should be remembered: (1) that optic neuritis is constantly present in tumours of the corpora quadrigemina; (2) that it is present in 89 per cent. of cases of cerebellar tumour and of tumours of the posterior part of the cerebrum; (3) that it is absent in nearly two-thirds of the cases of tumour of the pons and medulla and of the corpus callosum; and (4) that it is least frequently met with in cases of tuberculous tumour and most common in cases of glioma and cystic tumour.

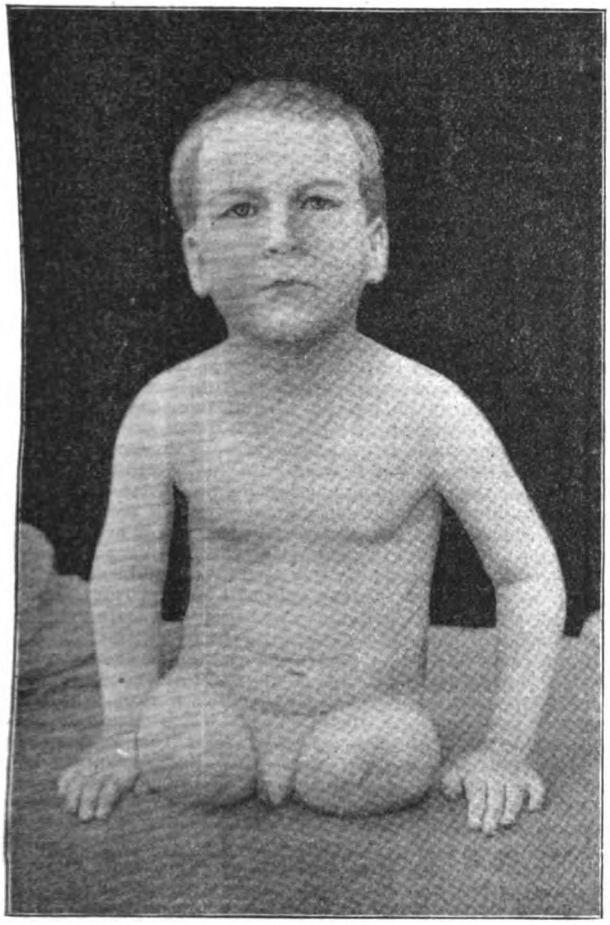
Brighton.

A CASE OF DRY GANGRENE OF BOTH LOWER EXTREMITIES COMPLICATING ORDINARY SCARLET FEVER; DOUBLE AMPUTATION; RECOVERY.

BY A. E. PEARSON, L.R.C.P. EDIN., M.R.C.S. ENG.,
MEDICAL OFFICER, LEEDS CITY HOSPITALS;
AND
H. LITTLEWOOD, F.R.C.S. ENG.,
HONORARY SURGEON TO LEEDS GENERAL INFIRMARY.



A BOY, aged four years, was admitted to the Leeds City Infectious Diseases Hospitals on Sept. 14th, 1896, suffering from scarlet fever. Malaise, headache, vomiting, and sore-throat occurred on Sept. 9th, the rash being first seen on the 10th. He had suffered from chicken-pox twelve months previously, and from measles three years before. It was elicited from the friends that the family were strongly susceptible to rheumatic affections, the father having died during an attack of acute rheumatism. A sister also had suffered from severe rheumatic fever. On admission the child presented nothing beyond the ordinary symptoms. The tongue was swollen, reddened, and showed enlarged papillæ. The tonsils were congested and œdematous, with small necrotic patches. There was also general faucial and pharyngeal congestion. The submaxillary glands were moderately affected, and a characteristic eruption was noted in the usual situations. On the 17th, being the ninth day of the disease, it was noticed that there were numerous small discolourations (which seemed to be subcutaneous hæmorrhages) extending in both lower limbs from the toes to within two or three inches of the knees anteriorly and posteriorly. At this time the faucial disturbance had very considerably abated, though congestion was still evident, a clean ulcer being noticed on each still slightly inflamed tonsil. The temperature was 101° F. Desquamation of cuticle was observed at the upper part of the chest and neck. Day by day the discolouration of the limbs became more marked, though still continuing to be somewhat patchy, lividity being most intense at the toes and feet, and becoming less so from below upwards. On Sept. 20th, a note informed us that the limbs retained a considerable degree of warmth, probably somewhat exaggarated by the more or less continuous application of artificial heat, and that in neither limb could pulsation in the femoral arteries be distinctly felt. The condition now appeared to give the patient considerable pain, apparently of an intermittent character, and the discolouration had spread to some four inches above the knees anteriorly and to slightly above the centre of the popliteal space posteriorly, the distribution being almost exactly similar in both limbs. From the 20th to the 25th the temperature subsided to normal, and the upper parts of these areas were less discoloured. On the 30th (twenty-second day) an oblique line of demarcation had formed, roughly extending in both limbs to three inches above the knees in front and to the centre of the popliteal spaces behind. At this time there was noticed some slight degree of cardiac dilatation, and a suspicion of roughness of the first sound at the apex. Mr. Littlewood saw the patient on this date, and advised amputation. On Oct. 3rd, after a brandy and milk injection per rectum, the patient was put under ether, and Mr. Littlewood amputated the right thigh by a modified circular operation. All the available healthy skin above the gangrenous part was retained, an incision being carried upwards on the outer side for some four inches. The femur was divided at about the junction of the middle and upper thirds. The blood was very thin, coagulating slowly and imperfectly. The femoral artery was patent. The patient tended several times to collapse, requiring subcutaneous injections of brandy. Silk-worm gut was used for stitches, and the dressings were cyanide gauze and iodoform. The patient recovered well from the operation, and though some rise of temperature was noted on subsequent days, it would appear to have been due to ulceration and some septic inflammation present at the line of demarcation separating the healthy and diseased parts in the other limb. The operation wounds of this amputation healed almost entirely by the first intention except at the outer angle formed by the flaps, where some slight sloughing took place. The parts were drained by indiarubber tubing for some ten days. On Oct. 10th, a week after the first operation, amputation through the left thigh was performed by Mr. Littlewood. The like anæsthetic precautions and incisions were taken and made. The patient bore this operation much better than the first. The wounds were similarly drained and stitched and they also healed by first intention. After the second operation the patient made rapid progress and was allowed to be wheeled about in the ward on Nov. 3rd. When seen later at his home the stumps were found to be well padded and furnished. The patient had free power of flexing, extending, abducting, and adducting the stumps, and would shortly be able to wear artificial limbs. The illustration represents the condition of the patient nine months after operation.

Description of the parts removed.—Both legs were dry and mummified, the skin having a yellowish translucent appearance. Just below the amputation line there was an ulcerated area of skin about half an inch wide and nearly surrounding the limb. On dissecting the vessels they presented similar appearances on both sides. The coats of the vessels appeared normal. In the popliteal arteries, about the middle of the popliteal space, was a soft, reddish-white clot, which did not fill up the whole lumen of the vessel. It could be easily separated from the intima, the clot being about an inch long. Below this to the bifurcation of the vessel there was some loose clot of similar appearance, but above the vessel was empty. There was no clot in the posterior tibials at the ankles. There was a clot in the popliteal veins at the same level as that found in the arteries. It was more like a venous clot, darker in colour, and quite filling up the lumen. It was not adherent to the intima. The clot in the right side appeared to be undergoing some decomposition changes. Both clots occupied about an inch of the lumen. Below this, in the tibial veins, there were some coagula of the same colour, but not filling up the

Digitized by Google

vessel. Above the clots the veins were empty, as also were the veins at the ankles.

Remarks.—This case appears to us to be of very considerable interest, and almost unique in its occurrence. It is of interest from two points of view—firstly, as an extremely rare complication in connexion with scarlet fever, and, secondly, from the infrequent occurrence of dry gangrene in so young a subject apparently free from diseased blood-vessels. We have been unable in searching the literature of the subject to find records of a similar case. Osler, however, incidentally mentions that symmetrical dry gangrene is a rare complication of scarlet fever, and there is to be found recorded in Holmes's "System of Surgery" a case of gangrene of the left leg complicating scarlet fever in a woman aged forty years. As to the *causa causans*, there would appear to be two factors which operated—an extremely thin and poor state of the circulating fluid and a debilitated condition

of the circulatory system from the specific febrile illness. The former was noted during the operation, and the latter was observed from physical signs during the illness and before amputation. It will be noted in the preceding account of the dissection of the limbs that the thrombosed clot was of some considerable extent in both the arterial and venous vessels of the popliteal areas. It might be urged that the clot was of embolic origin, occurring in a patient whose family were strongly predisposed to rheumatism. In this argument it should be remembered that though there was evidence of circulatory enfeeblement and cardiac dilatation there were no signs of gross valvular lesion, and that the clotting, though extending to the bifurcation, would seem to have commenced at the middle of the popliteal arteries. The vessels in the dissection showed no evidence of disease. Another point of some interest was the absence of any inflammatory disturbance in the wounds after amputation of the limbs, both operations having been performed whilst the patient himself was in an infective state and in close proximity to other cases of scarlet fever. The patient was, however, isolated in a disinfected room for the operations.

Leeds.

A NEW AND EASY METHOD OF EXAMINING MALARIAL BLOOD.

BY NEIL MACLEOD, M.D. EDIN.

FOR diagnostic purposes the examination of fresh malarial blood films immediately after preparation is without doubt most to be relied on. It is not always convenient, and in the midst of a large practice often very inconvenient, to make these examinations when the films are fresh, and thus one is driven to the examination of stained films at more convenient times. The staining of these films is to me, and I find to not a few others, an uncertain and troublesome process—that is, so far as results that can be relied on for diagnostic purposes are concerned. Dr. Reid, of Shanghai, two years ago suggested to me the examination of the dried, unstained film, having tried, but not having himself succeeded, in finding malarial parasites in this way. Drawing a cover glass across a drop of blood on the finger tip, as he suggested, I did not succeed in my quest; but some months later I did so without any difficulty by drawing across one cover glass the edge of another square cover charged with a blood drop. Since last August I have discarded the cover glass for a strip of ordinary notepaper for the purpose of spreading the film. I now carry in my pocket-book a sheet of notepaper one edge of which is snipped with scissors at intervals of half an inch, each snip being one and a half inches deep. The snipped edge is folded inwards to the middle of the sheet, the other half of the sheet being folded over all to keep the strips clean and ready for use. The straight edge of one of these strips is drawn its full half inch through a drop of blood on the finger tip not larger than the head of a pin, the finger tip and the cover glass being previously thoroughly cleansed in the usual way. If too much blood be taken on the strip the film will be too thick and useless. The edge of the strip is quickly drawn across the cover glass, the strip being held nearly at right angles to the surface of the glass and before the blood has had time to dry on the paper. In this way is spread on the cover glass (or slide, if preferred) a fine blood film which dries very quickly, and in it many excellent fields will be found with the corpuscles lying on the flat and practically unaltered. The cover glass must not be fixed to the slide by any medium which will run between the two, causing everything to disappear from view. It must be mounted dry. It can be gummed to the slide by a strip of thin paper with a window exposing the blood smear, when the latter can be examined with dry or immersion lens. With a good quarter inch objective crescents and the larger pigmented parasites, and with an oil twelfth the smaller pigmented forms, can easily be seen. The examination of a few specimens will acquaint anyone with their appearance, so that even beginners have little difficulty in finding these organisms. The specimens being thus preserved can be again and again examined, whereas with wet, fresh preparations a few hours alter them beyond recognition, and the cases are not at hand when study of the organism is convenient. It is well to compare the appearance of these organisms in the dried and undried state. *Particular* organisms can be studied in the dry film on the *slide*, their position located by means of a finder, and the organism in question stained and re-examined—a procedure, so far as I am aware, not yet recorded. The film on a slide can be examined with a dry lens without the intervention of a cover glass; then stained, dried, and examined without cover glass, or with a cover glass with or without balsam. If an oil immersion lens is to be used the film when dried and unstained ought to be on the cover glass, as the air layer intervening between the cover glass and slide, if the film is on the latter, prevents the oil lens working at its best.

The films should be carefully preserved from dust before they are mounted. Pill boxes serve this purpose well. The colour of the protoplasm of the parasite is not quite the same dried as undried, and, of course, no movement of parasite or pigment is possible in the dried state, but this presents no difficulty with pigmented forms. The unpigmented parasites cannot be detected even in the fresh undried film with certainty unless they are seen to move; but even these I have detected in the dried form as rings or signets and then stained them. This method, however, cannot be relied on for the detection of unpigmented forms of these organisms without very considerable experience.

Digitized by Google

and should be supplemented by staining or the examination of fresh undried films. For satisfactory work with either dry or wet lenses in examining these parasites a good sub-stage condenser saves much time and trouble.

Blood films treated as I have recommended are subjected to less interference than when fixed by heat, alcohol, ether, or other means, or when treated with one or more staining solutions, washed, dried, &c.—procedures which I have found to so alter and obscure parasites distinctly visible in the dried untreated film that they could not be recognised as the parasite previously seen except by their surroundings previously registered. While this may not matter in the histological study of these organisms it is somewhat different when diagnosis is concerned, where, as is not infrequently the case, the number of organisms circulating in the peripheral blood is small, and the less they are altered or obscured the better. I have specimens of these parasites of the most typical character preserved for demonstration purposes—no small advantage where demonstrations are wanted and no cases are at hand for that purpose.

Shanghai.

NOTE ON AUTO-INTOXICATION DURING PREGNANCY.

BY J. CHRISTIAN SIMPSON, M.D. EDIN.

IN Dr. Clifford Allbutt's interesting paper on "Albuminuria in Pregnancy"[1] some strong reasons are brought forward in favour of the toxic origin of this condition. Perhaps I may refer to some other points which seem to me to strengthen this position, more especially in connexion with two conditions—namely, salivation and eclampsia. In ordinary persons "a rush of saliva into the mouth usually precedes the act of vomiting," and the nausea or vomiting of pregnancy naturally has this as an accompaniment. But in certain cases the amount and persistence of the abnormal salivation are so marked that it seems to be an independent phenomenon rather than the accompaniment of the emesis. Without going into physiological details one may remark that according to Ludwig[2] "the saliva is really secreted from the lymph present in the lymph spaces of the gland." On the one hand "we may have secretion without a blood stream" through the glands; while, on the other hand, "if atropia be given to an animal, stimulation of the chorda tympani nerve produces dilatation of the vessels, but no secretion of saliva." It must also be noted that the secretion of saliva "is not a mere process of filtration, such as, perhaps, occurs in the glomeruli of the kidney."

The amount of saliva secreted by some pregnant women may reach many quarts in the twenty-four hours. This usually persists during the early months of pregnancy only, but in some instances it lasts up to the confinement and then disappears in the course of a few days usually, but Green[3] noted a case in which it persisted for two weeks. In any case its persistency marks a difference between this hyper-secretion from that known as "paralytic secretion," which only lasts about eight days. The hyper-secretion of pregnancy contains no ptyalin and a lesser amount of sodium salts than is in normal saliva; it thus resembles what is called "chorda saliva" rather than what results from stimulation of the sympathetic, except when this has been prolonged, for the saliva resulting from moderate stimulation of the sympathetic is scanty and contains a very large proportion of solids. Stimulation of some distant sensory nerves causes a secretion of saliva, and certain uterine conditions—even menstruation—have been considered to be a starting-point of this; in fact, such salivation is usually described as "a purely nervous disorder" which is not readily controlled by any antisialic or nervine sedative.

When one tries to explain salivation on a toxic theory what is found? According to Bouchard[4] one of the toxic principles in normal urine is a sialogogue, but salivation is not seen in experiments with ordinary urine as "the total quantity of urine sufficient to kill does not contain the sialogogue in sufficient quantity to produce its physiological effect"; but if urine deprived of a part of its toxicity, say, by decolouration, be injected salivation is one of the symptoms produced. By a process of exclusion, the details of which it is unnecessary to allude to, he has defined this toxin to be "a stable organic substance, not fixed by charcoal, soluble in alcohol, and distinct from the diuretic (urea) or the narcotic toxin." It is found in much greater amount in the blood, liver, and muscles than in the urine, but so far it has not received a name, and its chemical nature is unknown. Its effects are well seen in rabbits after intravenous injection of the alcoholic extract of normal urine, for salivation appears during the comatose state, persists for three-quarters of an hour, and is apparently equal to that produced by jaborandi. If alcoholic extract of blood be injected, muscular weakness, convulsions, and rapid salivation supervene. As this toxin is found in much greater amount in the blood, liver, and muscles than in the urine it is concluded that it is "from the blood that the kidneys get this substance which causes salivation."

In the case of eclampsia it must be noted that two convulsive principles are found in normal urine. One is a "fixed stable organic body, destroyed by carbonisation, yet retained by charcoal; it is insoluble in alcohol, as either a base or a salt, and may belong to the group of colouring substances." The other is fixed and inorganic, and is, in fact, potash. It is thus evident that faulty elimination of these products might be sufficient to induce eclampsia, but there are possibly other waste products which accumulate during the course of pregnancy, as will be seen later. In this relation it may be well to consider two primary and certain secondary sources of auto-intoxication. On the one hand, there may be a primary derangement of the liver, with secondary intestinal decompositions, and in due time renal irritation and insufficiency from absorption and excretion of toxins may appear and aggravate matters. On the other hand, a primary renal insufficiency may be so marked that if the hepatic and intestinal functions are slightly deranged serious symptoms may arise which might not have been induced had the kidneys been acting normally. The question whether intestinal derangement is an active factor in the case might perhaps be determined if it were possible to estimate the ratio between the free and aromatic sulphates in the urine. Hunter[5] in his researches on the causation of pernicious anæmia, showed that an increase in the ratio of aromatic over free sulphates is evidence of intestinal decomposition and putrefaction, and that "the destruction of blood was effected by the action of such poisons absorbed from the gastro-intestinal tract." But at the same time there must be a considerable latitude for both forms of insufficiency, for it is not every case with an inefficient liver or kidney or intestine that is attacked with eclampsia. As examples of these types one may quote Clark and Skelton,[6] who observed one case of eclampsia in which there was no marked renal insufficiency until after the seizures, though there was at the same time acetonuria. In another case there was marked renal inadequacy, but no fits occurred. They assume that the first case was due to hepatic derangement, as indicated by the presence of acetone in the urine. Vicarelli,[7] however, examined 137 patients and found acetonuria in 9, all of whom were delivered of a dead fœtus. The acetonuria disappeared in four days, but no mention is made of any eclamptic symptoms. Again, in close relation with acetonuria Stumpf[8] found that "the urine of eclamptic cases even before the attacks contains much more sugar than the ordinary urine of pregnant women," which doubtless results from hepatic derangement. An example of convulsions resulting from intestinal disturbance is given by Hirst,[9] who states that a young woman had violent convulsions the day after her confinement. There was coma, suffused face, very rapid and feeble pulse, and an elevated temperature. On examination of the urine nothing abnormal was found, and there was nothing locally abnormal per vaginam. She had been constipated for two days, however, so a purgative was administered; a good motion resulted, and she felt better very soon after.

As one of the convulsive toxins in the urine probably belongs to the group of colouring substances, the relation between hepatic and intestinal derangement and convulsions is intimate. Van der Velde[10] has recently recorded some

experiments undertaken with a view of elucidating "auto-intoxication gravidique." He found that pregnant rabbits were very much more sensitive to the action of normal human urine than non-pregnant animals. Thus clonic convulsions of the neck appeared after 23 c.c. of urine were injected, whereas 51 c.c. of the same urine produced no effect on non-pregnant animals. Again, the defibrinated blood of a pregnant rabbit induced convulsions when 18 c.c. per kilogramme had been injected, while with blood from a non-pregnant animal nothing happened until 25 c.c. per kilogramme were injected. When the urine of the same animals was injected, that of the pregnant one caused convulsions with 18 c.c. per kilogramme, while no convulsions followed the injection of the non-pregnant animal's secretion to the extent of 30 c.c. per kilogramme. He concludes that there is not only an exaggerated activity during pregnancy, but also an increased susceptibility of the nervous system to convulsive toxins, and that this does not cease immediately after labour. That this is so, and that the blood is the source of the toxicity, are shown by the facts that in one instance there was still rapid reaction to the injection of blood taken three days after labour, though the urine was not more convulsive than normal; and in another case the effects of the injection of blood were detectable even up to the eighteenth day after delivery. "There is thus a renal insufficiency which causes accumulation of toxins in the blood during pregnancy in addition to those found in normal urine, and the combined results may be seen in the symptoms of eclampsia." The occurrence of various neuroses in the puerperium has to be taken into consideration with this fact—namely, the toxicity of the blood developed during pregnancy does not disappear for nearly three weeks after the confinement. This term practically coincides with the involution of the uterus, which of necessity argues a great increase in the amount of waste products, which should be eliminated with the greatest possible efficiency. Therefore, any renal insufficiency will be a very important factor so long as the process of involution is taking place. The toxic theory of eclampsia is also supported by the occurrence of other affections of the nervous system in connexion with pregnancy or the puerperium. Whitfield[11] records a particularly interesting association in the case of a woman who had severe vomiting during the whole course of pregnancy. This ceased the day after delivery, but three days later symptoms of neuritis appeared. It was non-alcoholic in origin and the patient recovered completely. Desnos also noted "a case of muscular atrophy of the limbs of rapid evolution coming on during pregnancy after severe vomiting."[12] It seems to me possible that the severe muscular exertion during labour may in some cases be sufficient to determine such a puerperal neurosis. Given renal inadequacy, to a slight extent even, it is quite possible that a sudden accumulation of waste products may result from the severe muscular exercise in such a comparatively limited period of time. The altered constitution of urine after "fatigue drill" and the difference between the urine secreted during the day from that secreted during the period of sleep and rest are well known, and if neuritis can be caused by the faulty metabolism of gout, rheumatism, and diabetes, such an explanation of the origin of some cases of puerperal neurosis may be held. Some eleven years ago I saw a case of (?) progressive muscular atrophy in a woman. The symptoms began in the lower limbs, and she distinctly attributed the onset of the affection to the excessive muscular exertion and straining of the legs during labour, more especially as they were cramped up against the foot of the bed. Whether this might not have been an instance of puerperal neuritis I have now no means of determining, but it seems possible, and "some facts show that an ascending neuritis is able to be the starting point of progressive muscular atrophy,"[13] which has also been known to follow certain acute infectious diseases such as measles.

Seeing that the source of the auto-intoxication is in the blood, liver, and muscles, and that the symptoms arise in some cases apparently from primary hepatic and intestinal derangement and in others from a primary renal insufficiency, with or without marked hepatic and intestinal defection, what is a rational line of treatment? Practically it may be assumed that the majority of cases suffer from a combination of these morbid processes, and it may be advisable to regard salivation as one of the early danger signals in the course of the case. This is supported by the facts that Robin[14] has observed salivation in uræmia, Nothnagel[15] has seen salivation precede the convulsions of epilepsy, and Winder reports two cases of eclampsia, in both of which "the salivation was extreme, the bedclothes and pillows being absolutely wringing wet." The urine was albuminous and the placenta adherent in both instances.[16] Bouchard believes that "the skin and lungs cannot vicariously aid the kidney which has become incapable of accomplishing elimination." He has calculated that one litre of water per intestine is simply one litre less per kidney, which would have eliminated fifty times more urea as urine in the healthy state, but though diarrhœa does not remove urea from the blood it removes other poisons from it.[17] The line of treatment by hydragogues in uræmia is therefore based on a good foundation, but in no case should salts of potassium be used.

It has been shown that the toxicity of the bile and also of the urine is diminished by decoloration, hence the administration of charcoal is of value, as it acts by decolouring some of the pigments and by fixing others, thus removing a constant source of readily absorbable toxins. My experience of the administration of charcoal in colotomy and other cases has been most satisfactory. In addition to charcoal some other intestinal antiseptics may be used, such as naphthalin, &c., and if the liver is especially inefficient a mercurial will be of double service. As to diet, milk in small quantities and suitably given has the reputation of "being opposed to all sources of intoxication."[18] The lowered temperature such as occurs in instances of uræmia, especially in the comatose stage, is really an evidence of imperfect oxidation; Jaccoud[19] highly recommends inhalations of oxygen in such circumstances, and Macalister has recently reported a case.[20] Perhaps the best effects will be obtained in the case of eclampsia with marked renal insufficiency by combining oxygen inhalations with bleeding. Bleeding in uræmia and during pregnancy was common many years ago as a matter of routine, and after having been ignored more or less completely for some time it has again attained a certain position in therapeutics. It has been found that 32 grammes of blood contain 50 centigrammes of extractive substances, and as the daily elimination of these by the urine is 8 grammes this is equal to one-sixteenth of the daily total,[21] and probably even more in the pregnant state. It is certain that more extractives can be removed by bleeding than by any other channel except the renal, though even then it is somewhat indirect and takes more time. A loss of 32 grammes, which can be effected by two leeches, removes as much toxic matter as can be done by means of 280 grammes of a liquid diarrhœa, or by sweating to the extent of 100 litres.[22] Thus in emergencies bleeding is a most efficient remedy, and possibly the loss of blood which takes place naturally during labour may to some extent account for the more or less sudden disappearance of some toxic symptoms which have persisted during the course of pregnancy.

TWO CASES OF FRIEDREICH'S DISEASE.

BY T. ARMSTRONG BOWES, M.D. CANTAB.

ALTHOUGH a considerable number of cases of this disease have lately been recorded in medical literature, the two following cases are worthy of addition to the number, as one of them presents two features of interest—namely, a confinement and a fracture of the femur during the progress of the disease.

CASE 1.—In a woman, now aged twenty-nine years, symptoms of the disease commenced at the age of thirteen years with difficulty in walking, and although she was for some time an out-patient at a hospital she has since then become progressively more feeble. She is by no means undersized, and she has fair hair and blue eyes. Her features are a little coarse. Mentally she is inclined to hysterical symptoms, as evidenced by a desponding tendency as regards her condition, and she is apt on slight provocation to dissolve into tears, but in spite of this she is able to

Digitized by Google

appreciate a good laugh. She reads, writes, and crochets a little, and she is able to use a knife and fork, although there is some difficulty in accurately gauging the position of the mouth when food is conveyed to it on the fork. Sensation is generally good, and the patient considers that of the right half of the body to be more acute than that of the left. The only abnormality seems to be a deficiency of sensation in the feet and in the lower half of both legs, this being due apparently to the local condition of the skin and to deficient circulation. She cannot walk even with help, and on attempting to do so she drags her legs along the floor. The thighs can be flexed but not the ankles, the foot is extended, and flexion by manipulation of the ankle-joint is deficient. Irregular, jerky movements of the head and neck are present, but none of the legs, and none of the arms except on attempted action to lay hold of anything, when the object is often missed, and the same non-success attends an attempt to touch the tip of the nose with the finger, and the attempted approximation of the corresponding finger-tips of the two hands with the eyes closed, while she has sufficient control over her hands to be able to crochet fairly well. Her speech, though thick, laboured, and hesitating, is perfectly intelligible. The tongue is protruded straight, though there is the same jerky irregularity of it as is present in the head and neck. The plantar reflexes are increased, the knee-jerks are absent, and there is no ankle clonus. The rectal sphincters are natural, the bowels requiring an occasional aperient. The bladder shows no loss of control, but there are occasional attacks of retention of urine lasting for two or three days and requiring the use of the catheter, and her mental condition at these times has a tendency towards hysterical manifestations. These attacks of retention have been present for years, sometimes following menstruation, an otherwise natural function. There is no implication of the pupil, but nystagmus of slow character is present, being lateral in direction, brought into play by lateral movements, and not present when the eyes are fixed. Most of the power in the muscles of the lower extremities remains in the extensors of the thigh. The joints move freely except the ankles, flexion of these being deficient from shortening of the calf muscles. Knee-joint flexion and extension are easily performed by manipulation of the limb. The muscles are wasted, their place being apparently supplied intrinsically and extrinsically by a deposit of fat, which is present in good quantity over the external surfaces of the buttocks. The feet and the greater part of the legs are congested, thickened, and a little puffy, this condition being apparently induced by the helplessness of the limbs. The second and third left toes are a little webbed. The fingers share in the deficiency of circulation, but not to nearly so great an extent as the feet.

CASE 2.—The patient is thirty-four years of age and is the sister of the patient in Case 1. The symptoms commenced at the age of ten years with difficulty in walking. The patient is dark-haired, her complexion is muddy and thick, and she is of slighter build and less stout than is her sister. Clinically the patient resembles her sister in all respects as above detailed, but she differs in that her feet are less blue and œdematous, the condition extending only about three inches above the ankle-joint and not reaching nearly to the knee as in Case 1, and also that she has no attacks of retention of urine. Her grasp is strong when she lays hold of anything and she is able to make trimmings for the dead. She was confined on July 27th, 1882, the child, a male, being stillborn. Labour was premature (at the eighth month) and was followed by considerable hæmorrhage. At this time she could walk with difficulty. On Dec. 25th, 1895, she fell and fractured the neck of the left femur. It united firmly, but she has not recovered the previous use she had of the limb and it is now practically helpless, whereas the right limb can be flexed at the hip-joint. On examination the leg is an inch and a quarter shorter than the right. Flexion, eversion, and rotation outwards of the hip-joint are all deficient, and when lying on the bed the foot is everted. The great trochanter is a little prominent and somewhat thickened, and its upper extremity is higher than it should be. There is little difference in the circumference of the two limbs, as the right and left calves in greatest circumference measure respectively ten and three-quarter inches and ten and a half inches.

In both cases the heart, lungs, abdomen, and urine are natural, there are no visceral crises, and ocular paralysis is absent.

Herne Bay.

LOCAL HOT DRY-AIR TREATMENT IN ACUTE AND CHRONIC GOUT.

BY W. KNOWSLEY SIBLEY, M.A., M.D., B.C. CAMB., M.R.C.P. LOND.,

SENIOR PHYSICIAN TO OUT-PATIENTS AT THE NORTH-WEST LONDON HOSPITAL.

THIS new treatment of joint and other affections by the localised application of very hot dry air I fully described in THE LANCET of Aug. 29th of last year. Further experience has confirmed the promising results obtained in the variety of cases then recorded, and the opinion expressed with regard to them. I now wish to draw attention to the action and results of this treatment in a consecutive series of cases of gout, with the belief that the profession will welcome any advance in the present unsatisfactory method of dealing with a disease which directly or indirectly affects such numbers of individuals. The affected limb is left in a temperature of up to 300° F. from half an hour to an hour. During this time, first the limb treated, and then the whole body breaks out into a profuse perspiration, and the pulse, and to a lesser degree the respirations, are increased in frequency. The general effect on the system is considerable, and is evidenced by the fact that the body temperature is raised often one, two, or even more, degrees Fahrenheit, as shown by a thermometer placed in the mouth. In the series of cases of gout which follow no selection of patients has been made; all, therefore, which came for treatment are described in chronological order.

CASE 1. *Acute gout*.—The first case was a man, aged sixty-five years, who came under observation on June 3rd, 1896. The patient had suffered from acute attacks of gout on and off for many years, the attacks often lasting for several months. A year and a half previously he had had a bad attack of pneumonia followed by a prolonged attack of gout in both feet and one knee, which lasted for three months. The present attack had commenced a few days before in the left elbow, which became swollen and the skin tense, red, and very painful; the back of the hand was also swollen, the knuckles being hardly visible and the veins much engorged. After the first treatment by the hot air the parts about the elbow were not so tense, there was less œdema over the back of the hand, and the veins were not so distended. The patient had a return of the attack in the evening in the elbow, accompanied by severe pain; after a bath on the following day the elbow appeared less inflamed and could be moved better; the pain was also greatly relieved. On the evening of June 5th the arm again became more painful, but the patient had a good night; the following day there was some effusion into the tissues below the elbow. Treatment again produced considerable improvement of the parts. By June 8th the gout had quite subsided in the elbow; there was no pain or effusion left, and the joint could be freely moved. During the night the index finger became inflamed; this became more comfortable after treatment and the swelling rapidly subsided. The patient went into the country for a change. In April, 1897, the patient had remained quite well and had been free from attacks of gout since the treatment. During the treatment he was taking alkaline medicine and a saline aperient

CASE 2. *Acute, sub acute, and chronic gout associated with eczema*.—This patient was a lady, aged fifty years, who commenced this treatment on June 25th, 1896. There was no history of gout or rheumatism in the family; her father lived to the age of ninety years, and her mother lived seventy-three years and suffered from eczema. Her paternal great-grandfather lived to the age of 105 years. The patient when young had excellent health till the first attack of gout, twenty-four years ago, in the right great toe, when she was laid up for a fortnight. From this time she had recurrent attacks of acute gout every three or four months. For many years it was confined to the feet. It first appeared in the knees twelve years previously and in the hands for the first time seven years previously. The attacks had been much worse the last six years; she was often laid up in bed for from six to ten weeks, and in acute pain. Five years previously she had an attack of eczema in the feet, and this had troubled her on and off ever since, never having disappeared. Eight years ago the chalky gouty deposit in the right great

Digitized by Google

toe broke down and discharged for twelve months, and this place had reopened on and off several times since. In October, 1895, the deposit in the left index finger discharged for four months, and about the same time the left great toe also discharged. From October, 1895, to June 25th, 1896, the patient had been laid up in bed, being unable to move because of pain, although taking large quantities of medicine. The left index finger was much deformed, and chalky deposit was seen beneath the thinned skin. The little finger of the right hand was also much deformed; there was chalk stone deposit in the middle finger of the left hand. The left knee was extremely painful and tender, movement was very limited on account of pain, and there were some deposits to be seen and felt on the anterior surface of the patella. Both the feet were swollen and covered with an irritable form of eczema, which, especially on the left, extended some way up the leg; both great toes were much deformed, tumid, and inflamed, very red and acutely painful; they were both dislocated outwards and the left was discharging thick pus and chalky matter and looked very angry. There was considerable puffiness about the ankles and pain on the slightest attempt at movement. There were deposits in both ears. On June 25th the left leg was placed in the cylinder. The pain was soon relieved by the heat, and when taken out she was able to move the limb freely and could even walk on it without pain; the eczematous condition was also better. The next day she reported that she had slept all night, that the knee was almost well and the foot much less painful, and that there had been no irritation from the eczema, although for the first time for four months she had not used any ointment. She had a second bath and was again much relieved. She returned for a third bath on July 6th, when she reported that she had had another attack of eczema which was very distressing. After treatment the intense irritation was much relieved; the toe continued to discharge freely. The patient's foot was too bad to allow her to come for a bath from July 8th to 22nd, when, after a bath, the part was much better, and she felt very comfortable. By Aug. 20th the patient had had ten baths. The fourth finger was now decidedly smaller, and the chalky deposit in the knuckle of the second finger was dispersing. On the 25th the patient had her eleventh bath, and said she was able to play the piano for the first time for six months. On the 26th, after the twelfth operation, the following note was made: "The various chalky deposits are decreasing quickly and becoming much softer; the fingers are more flexible and the whole hands are of a much better shape." On Sept. 2nd the patient informed me that she had been trying her voice and had found that it was quite restored; she had not sung for eighteen months. She was also able to run up and down stairs; the hands continued to improve. On the 29th the patient had her twentieth bath. She had had a bad cold, and on the previous day, after doing some needlework, she felt a sudden sharp pain from the right shoulder to the tip of the second finger on the right hand, and this had become stiff and painful. Now the elbow was also painful, the tissues about it being tense and swollen, and tender to the touch. All these symptoms were much relieved by another application of the hot air. The next day she reported having had a good night, and there had been no pain in the finger or elbow since; she had been able to dress herself. On Dec. 16th the patient again presented herself, not having attended since September owing to numerous domestic worries. She had been well with the exception of an attack of pain under the knees and down the calves (? phlebitis) in November. At this time the patient was fairly well in herself, but had some gout about the ankles and heels; the eczema had quite disappeared from the feet. The right elbow was enlarged, red, and painful. On the 24th the swelling about the left elbow, which was present last time, had increased and had become extremely painful. On the 29th the patient reported that her left elbow was much less painful for two days after the last bath, but it had then again become worse; the right elbow had not since been painful. On the 30th the left elbow was very red, swollen, and painful over the olecranon process; there was also a good deal of pain up the arm (lymphatic) and also in the axilla. The pain and congestion of the whole was much relieved by the bath. The next day the patient reported that the elbow again became painful during the evening, but she had had a good night and was feeling much better. During the next few hours the left elbow kept very painful and the skin broke on Jan. 5th, 1897, and it then discharged slightly. A day or two afterwards the right arm became painful, then the left became still more inflamed, and the patient had to keep in bed. She had had no sleep for several nights, so she was taken in for treatment on Jan. 13th. The left arm, which was greatly inflamed and red from the elbow to the middle of the arm, was placed in the cylinder, after which the patient fell asleep. Having slept for three hours, she awoke feeling much more comfortable. She did not have a good night, the elbow discharged very freely a thick chalky material, but in the morning the swelling and inflammation had considerably subsided. The whole condition rapidly improved during the next few days. By Jan. 21st the patient was well and she returned home. The elbow had ceased to discharge and the movements of the joints were unimpaired. She stated that the last time her finger discharged it continued to do so for six months. In April, 1897, the patient had continued quite free from gout since January, and there had been no return of the eczema; her general health had also greatly improved.

CASE 3. *Sub-acute gout, chronic bronchitis, and albuminuria.*—This patient, who was first seen on Sept. 21st, 1896, had probably inherited gout from his mother's side of the family. This patient, a painter by trade, had had severe colic fourteen years ago, and was sixty-one years of age. The first attack of gout occurred ten years ago in the right foot, when he was laid up for a fortnight; a second attack came on three years later, and for the last three years he had had repeated attacks, especially in the ankles. When he came to the hospital the right foot was swollen, very tender, and painful, the skin being red and much inflamed; both legs were œdematous. Internal remedies were prescribed. On Oct. 12th the general condition was much the same. The cough and bronchitis continued troublesome, with a good deal of expectoration in the early morning. There were general bronchial rhonchi, especially at the right apex. The urine was clear, of specific gravity 1012, and contained albumin. The second heart sound was accentuated. The condition of the foot was much about the same, the patient being hardly able to get about, and then only with great pain. On the 13th the first hot-air application was given, no change being made in the medicines. The foot was much easier and he could move it more fully after treatment. By the 19th he had had three baths. The foot was much better, and the bronchitis was also much improved; there appeared to be less albumin than formerly. He had slept much better since the baths were administered. On the 20th the patient stated that his foot felt quite well; he had no pain whatever. He took a mixture of gentian and bicarbonate of soda all through the treatment.

CASE 4. *Acute gout.*—This case of acute gout in a man, affecting the left ankle, was greatly relieved by three baths.

CASE 5. *Acute gout.*—A man, aged forty-three years, was first seen on Nov. 13th, 1896. His father died from rheumatism and Bright's disease. Gout occurred for the first time ten years ago, and the attacks had been repeated at least once a year ever since. This attack came on two days previously with great pain, chiefly in the left foot. He was given an alkaline mixture of soda and gentian and the hot-air baths. The patient felt great relief from the first bath—he could bend the foot with comfort afterwards and the pain was much less. On the 15th the foot had been much better. There was no pain but some stiffness about the ankle when walking. After another bath the foot felt quite well and the stiffness had disappeared and did not return. On April 3rd, 1897, the patient wrote to say that he had not had a return of gout in the feet and had continued at work ever since the previous November.

CASE 6. *Acute gout.*—A man, twenty-four years of age, came under observation on Dec. 7th, 1896. There was no family history of gout or rheumatism. Fourteen weeks previously the patient had suffered from inflammation of the eyes, which lasted three weeks, followed by pain in the back, which kept him in bed for three weeks; afterwards the pain settled in the knees, the left big toe, and then in the left hand and arm. Between Dec. 7th and 21st he had four baths, and in addition a mixture containing bicarbonate of soda and iodide of potassium. By Jan. 4th, 1897, he was quite free from gout.

CASE 7. *Gout, bronchitis, heart disease, albuminuria.*—This patient, who was a woman, aged sixty-five years, came under observation on Nov. 23rd, 1896. Her maternal grandmother, who suffered from gout, died when over eighty, and her mother died at ninety-three years of age. She was quite

Digitized by Google

well till forty-three years of age, when she had the first attack of gout in the left great toe. She had had frequent attacks since in the feet, ankles, knees, elbows, and hands. For the last eighteen years she had also suffered much from bronchitis. On Dec. 8th she was admitted into the hospital. At this time the patient was very weak and suffered much from dyspnœa; the pulse was rapid (120) and small; the cardiac dulness was increased; there was a soft systolic murmur at the apex and a much louder one at the base, which murmur was readily heard in the vessels of the neck; the heart sounds were very feeble; there were general bronchial rhonchi over both the lungs. The urine was of specific gravity 1010, acid, and clear, and there was some albumin present. The feet were much distorted from old standing gouty changes; there was a large nodule in the left metatarsal phalangeal articulation of the big toe. There was very little movement in the knee-joints, and there was thickening about the heads of the tibiæ. The joints of all the fingers were enlarged, and the fingers deflected to the ulnar side. There was a large firm nodule over the right olecranon and hard nodules on the outer side of the olecranon of the left elbow. The patient had had little or no sleep for weeks, and the breathing was rapid and shallow. On Dec. 11th, after the first bath, the patient seemed to be a little easier. By the 14th the breathing was better after the bath, but she had not slept much. By the 21st the right hand was not so painful and the cough was a little easier; the patient still felt very weak, and her skin did not act well. She gradually improved, and left the hospital on Jan. 7th, 1897.

CASE 8. *Sub-acute gout.*—The patient, who was a cab-driver, thirty-eight years of age, was first seen on Jan. 4th, 1897. He was treated in the same way as the patient in Case 6, being given two baths, and by Jan. 14th he was free from pain.

CASE 9. *Acute gout.*—The patient, a woman aged sixty-two years, came to the hospital on Feb. 22nd, 1897, and gave no family history of gout or rheumatism. She had congenital absence of the first, second, and third fingers of the left hand. Eighteen years ago she had her first attack of gout in the right great toe, and she had had repeated attacks, often twice a year, ever since. The present attack came on a week ago in the left shoulder, then the right leg, and three days later the right hand became involved. The whole hand was much swollen, very red, and the skin much inflamed and acutely painful; there was some inflammation of the left ankle. She also suffered from chronic bronchitis. The first hot-air application was administered on the 23rd, with the result that the hand was less swollen and felt much easier after the bath. A second bath was given on the 25th. The fingers continued to be very stiff, but there had been much less pain in them. A third application was given on March 1st, when the patient said that she had slept much better and the pain had been much relieved. After this she considered herself cured and returned to her occupation on March 10th. On admission to hospital she was ordered 5 grains of iodide of potassium three times a day and ten drops of colchicum vine every night, and on March 1st she had an alkaline mixture containing five grains of iodide of potassium three times a day.

CASE 10. *Acute gout.*—This patient was a salesman, who came to the hospital on March 21st, 1897, suffering from acute gout in both hands, which was quite relieved by three baths and an alkaline mixture.

It is important to note that nearly all of the above cases were treated as hospital out-patients, and that therefore it was impossible to regulate or in any way control their daily habits as to diet, &c. Most of the patients were also only treated during an attack of gout; it was difficult to persuade them to undergo treatment by the hot air between the attacks, even with a fair expectation of keeping off a return of the disease. For instance, in Case 2, although many promises were made, something always interfered to prevent the continuance of regular treatment. In spite of the considerable shortening of the attacks and of the improvement in her general condition, freely admitted by the patient, only the return of pain would persuade her of the need to continue with the hot-air applications. My experience with these cases is that directly the pain subsides the patient returns to work, and neglects to take medicine or the ordinary diet precautions. The cases above described contain examples of gout in its various stages, from the most acute, through the sub-acute, to the very chronic, these latter, sometimes with acute exacerbations, occurring from time to time. Taking first the very acute attacks (Cases 1, 4, 5, 6, and 9), in all of these the local intense pain and congestion were almost immediately relieved by the hot air; very obvious difference in the appearance of the part was seen after the application, and the relief from the intense agony of an acutely inflamed gouty joint was most marked. But gout, like rheumatism, is always prone to reappear; and it was found in Cases 1 and 6, that the acute inflammation in the part first affected rapidly improved under the local treatment, and in the course of a few days another deposit, but one not necessarily so severe, appeared in another part, sometimes the corresponding limb of the opposite side. Treatment would again rapidly disperse this second deposit, and in no instance did it afterwards follow in another joint. It would seem that in nearly all the cases the attack under hot-air treatment was very much shorter than the previous attacks which had been treated only by internal remedies (Cases 1, 2, 4, and 5). Often, in fact, the attack which previously had lasted for weeks under this method lasted only for the same number of days. In some (Cases 2, 6, 8, and 9) internal medicines, such as small doses of colchicum and iodide of potassium, were also given; in others only a simple alkaline mixture (with possibly a slight aperient such as Condal water) was administered, as in Cases 1, 3, 5, and 10. Nevertheless, in all of these cases the relief from pain and the rapid and complete disappearance of the gout were most marked. Case 2 very well illustrates the treatment of very chronic gout, with gouty or chalk stone deposits; the deposit in one finger, for instance, being so bad that at one time the medical attendant had wished to amputate the digit, and yet after several applications of heat the deposit gradually disappeared, and so also the deposits about the heads of the larger bones became distinctly lessened.

A few remarks are necessary with regard to the mode of action of this treatment. The heat applied locally to the inflamed gouty part causes an increased circulation in the area, bringing a larger quantity of blood to the seat of the lesion and at the same time taking away a larger quantity of blood probably more or less saturated with the bodies causing the local deposits. These deleterious products being in the general circulation, so to speak, dissolved out of the seat of the inflammation should in the normal course of events largely find their way out of the body through the kidneys, hence all should be done during the course of treatment to assist these organs to act as freely as possible. Some interesting observations on this part of the subject have recently been made in the clinics of Professor Landouzy at the Laënnec Hospital, and Dr. Déjerine at the Salpêtrière Hospital, in Paris, who are experimenting with the Tallerman treatment, the results of which were published by Dr. Chrétien.[1] They found, for instance, that in one case of ordinary gout the daily elimination of uric acid, which after the fourth bath was 57 centigrammes, rose after the ninth bath to 89 centigrammes; and in another case of arthritis the daily co-efficient of urea had changed from 20 grammes 97 centigrammes before treatment to 25 grammes 50 centigrammes after the treatment had been administered. They also found an increased excretion of all the salts, especially the chlorides. This increased excretion through the kidneys is probably the explanation of the great benefit of this hot-air treatment in cases of gout. The results in the French hospitals were obtained entirely by this external method and without the exhibition of drugs of any kind. I feel no doubt of the great benefit this treatment will show in cases of what are described as "constitutional goutiness," without necessarily any local objective lesion.

Upper Brook-street, W.

[1] La Presse Médicale, Dec. 26th, 1896.

PAUPERISM IN THE WEST OF ENGLAND.—In the first half of 1896 a sum of £206,609 was spent upon in-door and out-door relief in the five south-western counties. This is an increase of £1250 for the corresponding period of 1895. Devonshire is the only county which shows a decreased expenditure, the decrease amounting to £1224. Devonshire spent £14,378 on in-door and £58,426 on out-door relief. Cornwall expended £5689 on in-door and £23,502 on out-door relief. Somerset's total represents an increase of 2·9 per cent. over the beginning of 1895, the sum in 1896 standing at £12,807 for in-door and £41,931 for out-door relief.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF PYÆMIA AND ACUTE SUPPURATIVE ARTHRITIS WITH COMPLETE RECOVERY OF THE JOINTS.

(Under the care of Mr. BUTLIN and Mr. LOCKWOOD.)

OF the many varieties of streptococcus infection our present knowledge seems to suggest that the serum treatment is of more value in the local forms, such as erysipelas,[1] than in those cases such as pyæmia, in which the infection is probably more general. In the following case, however, the earlier injections were distinctly followed by marked improvement. The result of the active treatment of the joints affected is extremely satisfactory, and contrasts greatly with the treatment of pyæmic joints a few years ago, when ankylosis was generally the best result that could be looked for after the infection of a joint with pyæmia. For the notes of the case we are indebted to Mr. J. Preston Maxwell, house surgeon.

A married woman, aged thirty-three years, was admitted to St. Bartholomew's Hospital on Feb. 13th, 1897, at the end of an attack of acute suppurative tonsillitis, which, she said, began three weeks previously. Almost from the beginning of her illness she had had various complications. The left knee-joint was acutely inflamed and full of fluid, but the skin over it was normal, and the slightest movement caused her intense pain. All the other joints were healthy. There was slight dulness with some pleural friction at the right base, indicating a pleurisy of the right side, which was said to have commenced soon after the tonsillitis, and was now subsiding. The heart was particularly examined and no murmur or dilatation could be discovered. The urine was acid, of normal specific gravity, and without any trace of albumin. Her temperature was 101·5° F., her pulse was 132, and her respirations were 34. It was clear that the disease in the knee-joint was both acute and progressive, and therefore it was decided to ascertain the nature of the fluid contained in it. In the evening of the day of admission an anæsthetic was given, and, the skin having been disinfected, the needle of a sterilised exploring syringe was introduced. Pus was withdrawn; it was thin and quite odourless (two peptone broth tubes and an agar-agar tube were inoculated with the pus, but nothing grew). An incision on each side was made into the knee-joint and the remainder of the pus washed out; the joint was syringed first with a solution of biniodide of mercury (1 in 500), and then with a weaker solution of the same antiseptic (1 in 4000). The synovial membrane was seen to be inflamed and the articular cartilages felt velvety. A rubber drainage tube was inserted on each side of the joint, a large dressing of iodoform, iodoform gauze, and sal alembroth wool was applied, and the limb was placed on a straight back splint. On the following day (Feb. 14th) the patient's condition was about the same, though her temperature was slightly lower (101°); the joint was still very painful. This was attributed to the continuance of septic inflammation and to the fact that the splint had to be removed for dressing and irrigation with biniodide of mercury solution (1 in 4000), which was done twice daily. Therefore on Feb. 15th an anæsthetic was again given and the knee-joint thoroughly irrigated with the weaker biniodide solution, a determined effort being made to disinfect the cavity of the joint. The limb was then swung on a straight back splint with a foot-piece, the splint being covered with a mackintosh to allow of daily irrigation without disturbing the limb. Before the anæsthetic was given it was noticed that there was a well-marked systolic murmur at the heart's apex. On the 16th the patient was worse. She was not sleeping well and her temperature had risen to 104·6°, the pulse was 140, and the respirations were 32. The pleural friction could no longer be heard at the right base, but it was very distinct at the left apex in front. In addition to the systolic murmur there was a distinct diastolic bruit to be heard at the heart's apex. She was taking fluid food fairly well and the bowels were acting naturally. On the 17th it was clear that her condition was becoming highly critical. Hitherto the absence of rigors had been a peculiar feature of the case, and even now she did not have a distinct shivering fit; she had felt alternately hot and cold during the night, and her temperature, which had rapidly fallen to normal, was again rising fast. Her tongue was dry, and since the early morning she had been retching and vomiting. Slight subsultus tendinum was observed, and purpuric spots were noticed over both hands and forearms and the right leg. Her mind was clear, and delirium was absent. Although there was no clear evidence that it was a case of streptococcus poisoning, yet the probability seemed so strong that it was decided to commence the administration of antistreptococcic serum. At 2.45 P.M. the first injection of the serum was given into the substance of the rectus abdominis, with marked effect. The temperature fell half a degree, to 99·6, the vomiting and retching ceased, the colour and aspect improved, the subsultus tendinum disappeared, and the tongue became moist. The respirations came down from 34 to 28 per minute, and the patient volunteered the statement that she "felt better." The knee looked well. (At this time blood cultivations were taken from the finger, but no growth was obtained.) At 8 P.M. another injection of 10 c.c. of the antistreptococcic serum was given. She was keeping better, but during the night the temperature rose steadily, and the injection seemed to have had but little effect. She did not sleep well. At 3 A.M. on the 18th a third injection of 10 c.c. of the serum was given into the rectus. At the time she was delirious, and the injection did not prevent the temperature rising steadily. At 8 A.M. a fourth injection of a similar quantity of serum was given with no apparent result, and at 4 P.M. a fifth injection of the same amount was administered. The patient was now delirious, passing everything under her, refusing medicine, but taking liquid food fairly well. The temperature was 102°, the pulse was 140, and the respirations were 28. The knee was still irrigated daily, and looked well. On the 19th she was still going down hill; the delirium continued and fresh purpuric spots had appeared on the right leg. Her face was sallow, and her eyes were sunken. The systolic murmur was still audible at the apex. At 11.30 A.M. 20 c.c. of antistreptococcic serum were injected into the rectus, but as this injection had no effect whatever on her condition, injections were now discontinued. She was ordered 5 grains of sulphate of quinine in half an ounce of brandy, to be given every four hours. She continued to grow worse during the day, and at 4 P.M. sudden paresis of the right side of the face appeared, with slight twitching of the muscles of the face and neck. She was semi-comatose. The knee, which was still irrigated daily, looked well. On the 20th slight improvement had set it, she was rational, the paresis and twitching of the face had quite disappeared, and there were no fresh purpuric spots. She had taken the quinine well and had no signs of cinchonism. The temperature was 103°. The improvement was maintained, and she slept fairly at night, and her temperature, pulse, and respiration hardly changed for the next three days. On the 23rd the right knee became full of fluid. It was explored, opened, and drained in the same way as the left. The pus was of the same kind and yielded no growth on cultivation. A splint like that used for the left leg was used for this knee also. Both knee-joints were irrigated daily. From this time the patient steadily improved. The temperature came slowly down to the normal, which it reached on March 12th. The quinine was discontinued on Feb. 26th. The drainage-tubes were removed from both knees between March 1st and 5th and the wounds were allowed to close. As soon as they were healed the splints were removed and she was encouraged to use and bend the knees as much as possible. Massage was also employed. After the falling of the temperature she began to put on flesh and rapidly improve in her general health. By April 15th she could walk round the ward unaided, except by a stick, and could bend her knees through an angle of 70°; all the purpuric spots had quite disappeared, and no heart murmur could be heard. She was then discharged from the hospital; about the middle of May she was

[1] Marmorek: Annales de l'Institut Pasteur, Nov. 7, 1895, and Tison: Journal de Médecine de Paris, April 26th, 1896.

Digitized by Google

seen again, when she walked well without a stick and no defect was noticeable in her gait.

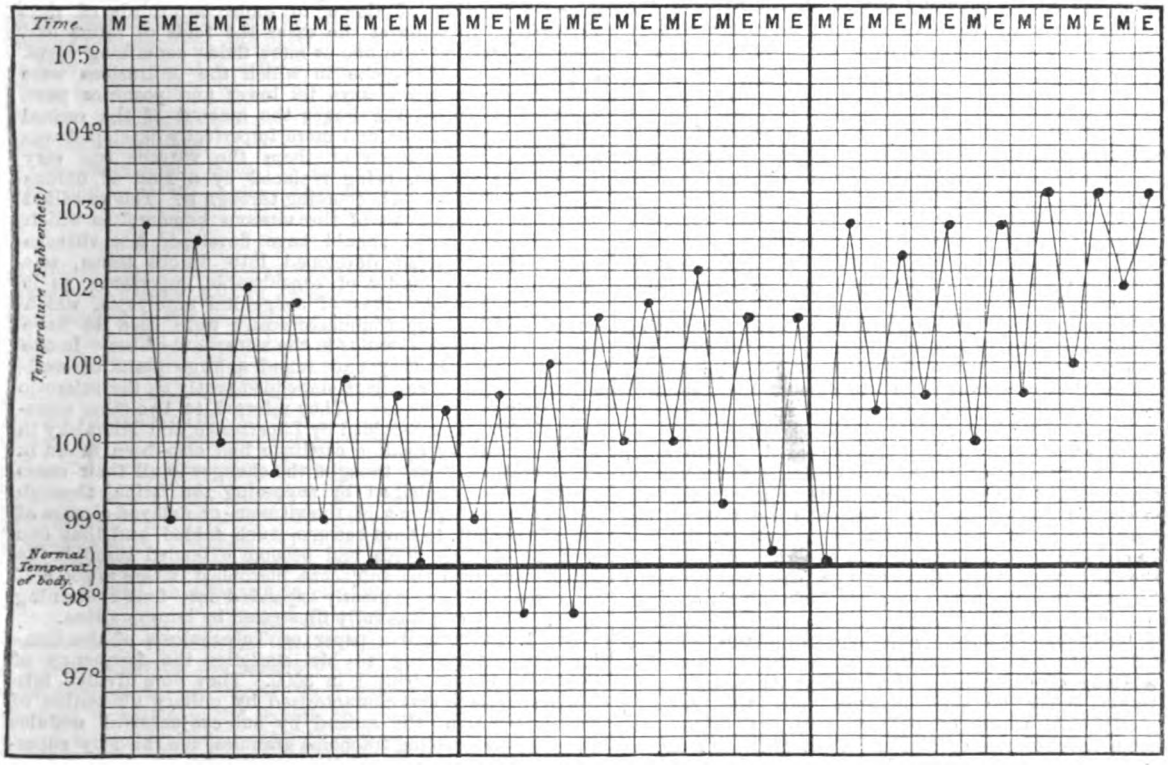
Remarks by Mr. LOCKWOOD.—It would hardly be right to draw any conclusions from this case as to the value of the serum which was given. I had not the opportunity of seeing the case when the joints were incised, or of seeing specimens of the pus. The fact that nothing grew in the cultures must not be taken to be evidence of the absence of streptococci. At times these organisms are exceedingly difficult to cultivate, although known to be present. Nevertheless, in this instance, some entirely different microbe may have caused the suppuration. The point of interest is the wonderfully complete recovery of function in the suppurating joints. This is due to the prompt treatment which the house surgeon, Mr. Maxwell, applied, and to the care which was afterwards taken to avoid any fresh infection from the wounds. Perhaps I may add that antistreptococcic serum was quite unavailing in a case of pyæmia which I saw with Dr. Samuel West and Dr. J. A. Smith, although streptococci were seen in the pus.

CANNING TOWN MEDICAL MISSION HOSPITAL.

A CASE OF ULCERATIVE ENDOCARDITIS TREATED WITH ANTISTREPTOCOCCIC SERUM.

(Under the care of Dr. MARGARET PEARSE.)

THE ordinary medicinal treatment of ulcerative endocarditis is so extremely unsatisfactory, and the rarity of recovery is so great, that any method which offers better prospects of cure is sure of a careful and extended trial. Though for years the causal connexion of streptococci and staphylococci with the disease has been recognised, it is only recently, since the introduction of serum therapy, that any hopes have arisen of combating successfully this most deadly disease. The use of antistreptococcic serum is still on its trial, and therefore every case in which it is employed should be put on record to assist in the formation of an opinion as to the value of the treatment. A case very similar to the following was published in THE LANCET last autumn.[1]



A girl, aged sixteen years, attended as an out-patient on Nov. 27th, 1896, complaining of having "had a cold" for three weeks and of her "breath being tight." There was marked dyspnœa, the pulse and respiration rates were increased, and the temperature was 101° F. Examination revealed rapid and exaggerated cardiac action, a loud mitral systolic murmur, and a faint diastolic murmur at the aortic area. The patient was put on salicylates and treated at home for a week. The temperature remained high, one evening rising to 105°. No improvement taking place she was admitted into the hospital on Dec. 4th. The history of the case obtained after admission was as follows. She had felt quite well till the commencement of November, when she "caught a bad cold that left her chest choked up." She kept at her work, though feeling ill, till Nov. 23rd, when she complained of aching pains in the left shoulder, and on the 25th of palpitation and shortness of breath. On the 27th she visited the out-patient department for advice. No previous history of rheumatism was obtainable, or of any rheumatic manifestations beyond a transient erythema a year before. On admission the patient did not seem to be very ill, being bright and lively. There was considerable dyspnœa, but she was able to lie down. She complained of palpitation and of slight pain in the left shoulder. There was considerable perspiration without acid odour. No nodules, no rash, and no anæmia were present. On examining the heart the apex beat was seen and felt in the fifth interspace, three inches from mid-sternum. The area of cardiac dulness was increased to the right. The sounds were muffled at the apex, but a mitral systolic murmur was distinguishable, as well as a diastolic aortic murmur, and some pericardial friction sounds. At the base of the right lung dulness on percussion and diminished breath-sounds indicated a small effusion. During the first week after admission, from Dec. 4th to 10th, the patient showed signs of marked general improvement. The dyspnœa lessened, the slight joint pains disappeared, and the temperature gradually fell from 103° to 100·4° in the evening, and reached the normal in the morning. The pulse-rate fell from 114 to 84 and the respirations from 36 to 24. Some progression was apparent in the physical signs, however, indicating especially increase of fluid in the pericardium. The apex beat was indistinctly felt in the fourth interspace, the area of cardiac dulness extended up to the second interspace, and the sounds at the apex became more muffled. A systolic aortic murmur was heard as well as the diastolic aortic murmur. The edge of the spleen was indefinitely felt below the costal margin. The patient during this time was at first taking ten-grain doses of salicylate of soda every six hours, and then every four hours. During the second week, from Dec. 11th to 17th, the general condition of the patient remained much the same, except that the temperature again gradually rose to reach 102° in the evening and an erythematous rash appeared which by degrees spread over the limbs and face, disappearing after three days. The fluid in the pericardium and at the right base diminished slightly in amount. The urine was normal, and continued so throughout the whole illness. During the third week, from Dec. 18th to 24th, she did not complain of feeling more ill, but the temperature now remained persistently between 101° and 103°, and the pulse-rate again rose to 116. She complained of tenderness on palpation of the spleen. The physical signs remained much the same, but for again indicating slight increase of fluid in the pericardium. As the salicylate treatment seemed to be useless the patient was given five grains of salol twice a day, but the treatment had to be discontinued after two days on account of the severe abdominal pains felt immediately after each dose. On the 24th she was seen in consultation by Dr. Schorstein, and as the increasing severity of the symptoms suggested the probability of the endocardial mischief having assumed a malignant type, it was decided to try the effect of treatment by antistreptococcic serum. An abstract of the daily notes is as follows, and the accompanying chart indicates the wide range of the temperature.

The serum used was obtained from the British Institute of Preventive Medicine, and the injections, with two exceptions, were made under the skin of the abdomen. All other drugs were discontinued. On Dec. 26th the patient complained of pain over the præcordium. Many fresh friction sounds were heard. The area of splenic dulness was increased downwards and forwards, and there was tenderness on palpation. At 6 P.M. 2½ c.c. of antistreptococcic serum were injected. She felt no discomfort either generally or locally afterwards. During the evening sharp pleuritic pains were felt in the left axilla, and many friction sounds were heard. On the 27th all pains had disappeared. At 8.30 P.M. 5 c.c. of the serum were injected. On the 28th the patient was much the same. At 6 P.M. 10 c.c. were injected. On the 29th her general condition was good, though the temperature remained high, and there was no improvement in the physical signs. There was still a considerable amount of fluid in the pericardium, and some effusion at the right base as well as the recent pleurisy on the left. On the 30th her general condition was not so good. She slept during the greater part of the day, but complained of pain over the præcordium and of very sharp pleuritic pains in the left side. Many friction sounds were heard. At 11 A.M. 20 c.c. were injected. There was no discomfort. On the 31st the temperature had made a decided drop, falling to 100°, and at 11 A.M 10 c.c. were injected. On Jan. 1st, 1897, there was an erythematous blush over the abdomen at the site of the last three punctures. Some improvement had taken place in the physical signs; the upper limit of the cardiac dulness was half an inch farther down, and there was less pericardial friction. The breath sounds were louder at the right base. Dulness and bronchial breathing at the angle of the left scapula and many friction sounds in the axilla were noted. On the 2nd the rash over the abdomen had not faded, and a rash showed itself on the limbs and face similar to that which appeared before. It was much more raised than that upon the abdomen which followed the injections, and was very irritable. On auscultation the second sound at the apex was found to be reduplicated. On the 3rd the temperature fell for the first time to normal. The injections were resumed after having been omitted for two days on account of the rash. At 10 A.M. 20 c.c. were injected, and within four hours the temperature rose to almost 104°. On the 4th there was marked general improvement in the patient. Her appetite was increasing. She felt no pains except a little at the site of the previous puncture in the gluteal region. On the 5th the temperature was normal during the greater part of the day, and did not rise beyond 101·6°. On the 6th the rashes had almost disappeared. The patient seemed to be decidedly stronger. There was marked

[1] THE LANCET, Oct. 17th, 1896, p. 1079.

Digitized by Google

improvement in the physical signs. The apex beat was now in the fifth interspace and the sounds at the apex were much less muffled. Much pericardial friction was heard. The breath sounds were distinct to the base of the right lung and the patch of bronchial breathing left had disappeared, but some friction and moist sounds were still heard. At 4 P.M. 10 c.c. were injected. On the 7th there was a slight rise of temperature in the evening and the pulse and respiration rates increased. During the night the patient was disturbed by uncontrollable cough; there was no expectoration. On the 8th the temperature fell below normal and the patient perspired profusely. At 10 A.M. 10 c.c. were injected and much pain at the site of puncture was complained of afterwards. Between 10 and 12 P.M. the temperature rose to 105° and the cough again became troublesome. On the 9th there was further improvement in the physical signs. The area of cardiac dulness was practically normal, except that the right limit was at the right sternal border. The apex beat was in the fifth interspace three inches from mid-sternum. The sounds at the apex were no longer muffled, and a faint

presystolic murmur was distinguishable. On the 11th the patient was very well and felt no pains. The temperature remained subnormal all day and did not again rise above normal. On the 23rd the patient was practically well and said she felt quite strong. There was no dyspnœa or palpitation. On examination all that was found was that the cardiac dulness still extended to the right border of the sternum, and that a double aortic and a mitral systolic murmur were present. The presystolic mitral murmur had quite disappeared. The patient was allowed to get up on this date, and on Feb. 5th she was discharged perfectly well.

Remarks by Dr. MARGARET PEARSE.—The foregoing account speaks for itself of the value of having adopted the serum treatment. Salicylates, after producing temporary improvement, proved useless. Salol could not be borne, and the case assumed an increasingly serious aspect until the injections were commenced and persevered with, for improvement even then was slow and gradual, though ultimately ending in perfect recovery. As to the diagnosis of the case it was difficult to arrive at any other. The illness was distinctly rheumatic in origin, as evidenced by the joint pains and the implications of both pericardium and endocardium. With the diminution of joint pains temporary improvement occurred, but this was soon replaced by progressive increase in the seriousness of the patient's condition. The temperature persistently rose and failed to be accounted for by the appearance of fresh rheumatic manifestations (beyond an erythema), or sufficiently increased severity of those already present, except as regards the endocarditis. Here, as the notes show, soon after the patient's admission into hospital a systolic aortic murmur gradually appeared, and later a presystolic mitral murmur, which afterwards gradually disappeared as the serum treatment was persisted in. This marked alteration in the murmurs, coupled with the high temperature of a hectic type and increase in the size of the spleen, led to the conclusion that the endocarditis was of the ulcerative rather than the simple type. Unfortunately, a bacteriological examination of the blood was only made on Jan. 11th, when, as the report said, "the case having been under treatment so long it was not surprising that no streptococci were found." The verification of the diagnosis by the appearance of infarcts was fortunately averted by putting the patient under the serum treatment immediately the diagnosis seemed in the least warrantable. The possibility of typhoid fever was readily excluded by absence of all the characteristic symptoms except high temperature and slight increase in the size of the spleen. Acute tuberculosis was still less closely simulated, and the issue of the case decided against the possibility, even had there been any doubt.

CITY ORTHOPÆDIC HOSPITAL.—The forty-sixth anniversary festival dinner in aid of the funds of this institution was held on June 30th at the Holborn Restaurant. The chairman, Baron Ferdinand de Rothschild, in proposing the toast of the evening, "The City Orthopædic Hospital," said the institution was face to face with the fact that it had to renew a mortgage of £6000, the committee having acquired the freehold of the hospital; they had, further, to appeal for funds to enable them to open additional wards. During the forty-seven years that the hospital had been in existence it had relieved upwards of 70,000 indoor and outdoor patients. It was also a free hospital and one that specially treated children. Subscriptions and donations were announced amounting to £1400, including 50 guineas from the chairman, 100 guineas from Baroness Hirsch, and 50 guineas from the City Corporation.

OPHTHALMOLOGICAL SOCIETY.

Spontaneous Dislocation of the Lens into the Anterior Chamber.—Demonstration of Tscherning's Theory of Accommodation. — Microphthalmos with Cystic Protrusion from the Globe.—Tuberculosis of the Conjunctiva.—Exhibition of Specimens and Cases.

A MEETING of this society was held on July 2nd, Mr. E. NETTLESHIP, President, being in the chair.

Mr. BICKERTON read notes of two cases of Spontaneous Dislocation of the Lens into the Anterior Chamber. In the first case (a woman, aged sixty-five years) the right eye had been lost by an injury twenty-five years before. The sight of the remaining eye failed suddenly one afternoon without any injury being received. She was not seen till seventeen days later, when there was raised tension, vision *nil*, the anterior chamber being occupied by a partly opaque lens. The lens was removed without difficulty by a vectis through a corneal incision. In the second case (a man, aged sixty-six years) cataract extraction had been performed on the left eye in 1891, a preliminary iridectomy being done on the right at the same time. In March, 1897, the lens was found filling the anterior chamber of the right eye, no injury having been received. Tension was + 3, and vision equalled doubtful perception of light. The cataractous lens was removed through a corneal incision; the cortex was fluid. The vision with correction after eighty-one days was $\frac{6}{9}$.

Mr. PRIESTLEY SMITH showed a model illustrating Tscherning's Theory of Accommodation, and reviewed the evidence for and against the theory. Helmholtz proved an increase of lens convexity in the area of the undilated pupil; he inferred a general increase of sphericity due to slackening of the zonula. He put forward his theory as provisionally the most feasible, not as proved. Tscherning, following Thomas Young, shows that during accommodation the refraction and the convexity of the lens increase chiefly at the central area of the pupil, less and less towards the periphery, and in the peripheral zones not at all; the lens surface changes from a spherical to a hyperboloid curvature. He shows further that this change can be produced in animals by tightening the zonula. Tscherning's observations relate to:—*1. Spherical aberration:* Did the sphericity of the lens increase during accommodation, the spherical aberration, other things being equal, would increase also. But a study of diffusion circles and shadows cast upon the retina shows no such increase, but the reverse; the peripheral zones of the lens do not increase in refraction as does the central area. *2. Scheiner's experiment:* Looking at a point of light through two adjacent pinholes placed before the pupil, the eye sees it single at the distance for which it is focussed and double at any greater or less distance. With an instrument based on this principle the refraction is estimated in different parts of the pupillary area at the same time. During accommodation the increase of refraction, measured in this way, is much greater at the centre than at the periphery. *3. Reflection from the lens surface in the living eye:* A series of electric lamps placed in a horizontal line before the eye are seen reflected by the lens. The varying degrees of displacement which these reflections undergo during accommodation are an index to the change of curvature in the lens surface. The convexity increases chiefly at the centre, less and less, or not at all towards the periphery. *4. Reflection from the surface of the exposed lens and traction of the zonula:* The zonula being seized and rendered tense at two opposite points of the circle, the change of curvature occurring in the lens surface is studied by means of images reflected from it in several zones. It is of the character already described. Tscherning holds, therefore, that in the act of accommodation the ciliary muscle contracts so as to increase the tension of the zonula, and to alter the lens surface from a spherical to a hyperboloid form. A given increase of convexity in the central area involves much less change the general form of the lens than it would according to the assumption of Helmholtz. Tscherning founds his study on the work of Thomas Young, and does full honour to that eminent man of science. Hess, on the other hand, shows that during strong contraction of the ciliary muscle, especially under eserine, the lens becomes tremulous, and this he declares is incompatible with an increased tension of the zonula. Tscherning confirms the observation, but attributes the trembling of the lens to spasmodic action of the ciliary muscle. Hess replies that the lens, besides being tremulous, is displaced laterally, the displacement in all positions of the head being governed by gravity. This, he urges, can only be explained by assuming that contraction of the ciliary muscle slackens the zonula.

Mr. TREACHER COLLINS and Mr. J. R. ROLSTON read a paper on Microphthalmos with Cystic Protrusion from the Globe, based on the pathological examination of seven eyes in which it was present. It was pointed out that though all the specimens were alike in one particular—namely, in being microphthalmic eyes with a protrusion of retinal tissue through a gap in the choroid and sclerotic—they presented great differences as regards the degree of development of the eyeball. The amount of the protrusion of retina varied from a small knuckle of tissue to quite two-thirds of that membrane. In some of the cases the folds of retina had become distended into one or more fluids containing cysts. The region of the globe in which the protrusions were situated was nearly always its lower and posterior part. Speaking generally, the larger the amount of the retinal protrusion the smaller and more imperfectly developed was the eyeball. In some of them the vitreous was very imperfectly formed, being replaced by a kind of fibrous tissue with blood-vessels coursing through it. This so-called "atypical development of the vitreous humour," in which the mesoblast which should have developed into vitreous humour had instead developed into fibrous tissue, was thought to be a matter of considerable importance, as it served to elucidate cases of congenital amblyopia, which when examined ophthalmoscopically were seen to have fibrous membranes or bands in the vitreous chamber. In one of the specimens they had found a large plate of well-developed hyaline cartilage embedded partly in the sclerotic and partly in the cornea. They referred to two other somewhat similar cases recorded by Lapersonne and Mitvalsky in which nodules of hyaline cartilage had also been found in the sclerotic. It was thought the changes in all their cases could be best explained by supposing the retina, through imperfect development of the vitreous or delayed closure of the ocular cleft, to have become much folded, and that one or more of these folds had become extended through the ocular cleft into the subjacent mesoblast, where in some of the cases it had subsequently expanded into fluid-containing cysts. The paper was fully illustrated by lantern slides.

Dr. J. EYRE read a paper on Tuberculosis of the Conjunctiva. According to his statistics the frequency of these cases was about 1 in 3000. They were divided into five groups—the first characterised by miliary ulceration of the conjunctiva, the second by sub-conjunctival nodules somewhat resembling trachoma granules, the third by superabundant papillary granulations, the fourth appeared as lupus of the conjunctiva, and the fifth as papillomatous tumours of the palpebral conjunctiva. The affection was to be regarded as the result of direct inoculation and not as an expression of general tuberculosis. The age limit varied from ten months to thirty years, the most common time of appearance being about puberty; females were more often attacked than males. The conjunctiva of the lower lid was the most common seat of the affection; glandular enlargement was generally present. Eight cases were described in detail. In group 1, 1 case; group 2, 2 cases; group 3, 2 cases; group 4, 1 case; and group 5, 2 cases. Special attention was directed to group 5 on account of the difficulty in diagnosis without microscopic examination. The necessity of early complete removal of the disease was insisted on.

The following cases and card specimens were shown:—

Mr. JESSOP: Sarcoma of Choroid.

Dr. BATTEN: Case of Spontaneous Hæmorrhage into the Vitreous.

Mr. J. GRIFFITH: Case of Probable Thrombosis of the Cavernous Sinus.

Mr. HOLMES SPICER and Mr. DEVEREUX MARSHALL: Specimen of Tubercle of the Iris.

Mr. THOMPSON: Unusual Type of Corneal Infiltration.

Reviews and Notices of Books.

Manual of Bacteriology. By ROBERT MUIR, M.A., M.D., F.R.C.P. Edin. (Lecturer on Pathological Bacteriology, University of Edinburgh; Pathologist, Edinburgh Royal Infirmary), and JAMES RITCHIE, M.A., M.D., B.Sc., (Lecturer in Pathology, University of Oxford). Pp. 519. 108 Illustrations. Edinburgh and London: Young J. Pentland. 1897.

BOOKS for students and practitioners on bacteriology now abound, and it is difficult to recommend any particular text-book. Some are too large for the general use of students and others are too meagre, and, in order to publish the work at a low price, illustrations are omitted. Without suggesting a slight to other similar works, we can strongly advise those who desire a text-book of convenient size, with lucid descriptions and good illustrations, to obtain the book now under consideration. The authors state in their preface that they have made an endeavour to render the work of practical utility for beginners, and have considered only those bacteria which are associated with disease in the human subject. This is, of course, all that is required by the student, and we congratulate the authors on having so successfully carried out their intentions.

To quote again from the preface: "In the systematic description of the various bacteria an attempt has been made to bring into prominence the evidence of their having an etiological relationship to the corresponding diseases, to point out the general laws governing their action as producers of disease, and to consider the effects in particular instances of various modifying circumstances." As regards this, also, the authors have produced most satisfactory results. The first chapter deals with General Morphology and Biology of Bacteria, and an interesting account is given of the structure of the bacterial cell, the modes of multiplication, and the chemical composition of micro-organisms. Then follow in succeeding chapters the modes of cultivation of bacteria, microscopic methods employed, the methods of inoculating animals, and general considerations of bacteriological diagnosis. The manner of preparing artificial culture media are duly described, and the student ought to find no difficulty in carrying out the instructions given, although, of course, a written description can never satisfactorily displace practical instruction.

The chapter on the Relations of Bacteria to Disease and the Production of Toxins by Bacteria, will well repay perusal, as will also the section on Immunity. The various theories of acquired, artificial, and natural immunity are clearly set forth and discussed, and the authors conclude the subject by admitting that the whole question is still an open one and cannot be fully explained. The descriptions of the individual bacteria are very clear and concise, and will be found useful not only by students, but also by practitioners as a means of acquiring practical knowledge which was not taught at the schools when they were students, but which, as given in this work, they will have no difficulty in adapting to their every-day work, so far as simple appliances will enable them to do.

Separate chapters are devoted to Acute Pneumonia, Tuberculosis, Glanders, Leprosy, Actinomycosis, Anthrax, Typhoid Fever, Diphtheria, Tetanus, and Cholera, whilst other pathogenic bacteria such as those of influenza, relapsing fever, plague, measles, &c., do not require such a long description. A good account is given of the micro-organisms associated with gonorrhœa and syphilis. Suppuration and allied conditions also receive due attention.

The authors "are convinced that to any one engaged in practical study photographs and photomicrographs supply the most useful and exact information"; they have consequently used these almost exclusively in illustration of the systematic description. We quite agree with the authors in the above statements. The photomicrographs are beautifully reproduced and greatly add to the general value of the work.

A Guide to the Clinical Examination of the Blood. By RICHARD C. CABOT, M.D. With coloured plates and engravings. London, New York, and Bombay: Longmans, Green, and Co. 1897. Pp. 405. Price 16*s.*

ANYONE who had been told twenty years ago what important diagnoses or aids to diagnosis can be derived to-day from the minute study of a single drop of blood might well have stood excused for incredulity. A new branch of pathological science has grown up, and its literature is so large and so rapidly increasing that practical workers will be grateful to Dr. Cabot for a book of moderate size in which may be found a good description of the methods which are in use, the main facts which have been ascertained, and their clinical significance. The plan of the book is strictly clinical, and the statistics given are largely from American sources. The author's extensive practical experience of the subject is everywhere apparent, and has been gathered, we read, chiefly at the Massachusetts Hospital. The clinical study of the blood is, indeed, much more extensively practised in America and on the Continent than is the case in this country, and it may be hoped that the appearance of so thoroughly practical a manual as the present work—the first of its kind, so far as we know, in the English language—may give an impetus to a study not merely interesting in itself but of profound value and importance to the physician or surgeon. Part I. deals with the technique of clinical examination of the blood, and the details given are clear and adequate. The author gives good reasons for preferring the lobe of the ear to the finger as the source of the drop of blood. The examination of the fresh blood, the use of the hæmocytometer, and of Fleischl's hæmometer are described in full, together with the best methods of preparing and staining blood-films. Part II. is devoted to an account of normal blood and its variations—a very necessary prelude to the study of pathological conditions. The description is in most respects admirable, but we cannot follow the author in his assumption that the varieties of leucocyte present in normal blood represent merely phases in the life-history of individual corpuscles. It is, of course, possible that such may be to some extent the case, but the relative infrequency of intermediate forms is an argument in the other direction. To describe the eosinophile cells as leucocytes in a state of senile decay is in our opinion unwarrantable, and is opposed to what we know alike of their physiological properties and of their history in animal phylogeny. In Part III. the author treats of the general pathology of the blood, anæmia, leucocytosis, and so forth.

The second and larger part of the book is occupied by the special pathology of the blood. The primary anæmias and leukæmia receive very full and thorough attention. These chapters are followed by an account of the blood in acute and chronic infectious diseases and in diseases of the different organs of the body. Here, though absolute diagnosis can rarely be made by the examination of the blood, yet very important indications are not seldom afforded by it, and the book is a useful work of reference in this connexion. The parasites of the blood are dealt with in a succeeding chapter and the book concludes with a section on the blood in infancy. Throughout the work very extensive references are given to the statistics and observations of European workers in the field, whereby the mass of information is much increased. It is to us a matter for regret that Englishmen have contributed so little, but we think that perhaps more attention might have been paid to some very valuable work which has emanated from this country. The

Digitized by Google

book is illustrated by a number of excellent coloured plates and is well got up. It supplies a distinct want in our literature and the author deserves hearty congratulation upon the success with which he has accomplished his task.

Practical Points in Nursing, for Nurses in Private Practice. With an Appendix Containing Rules for Feeding the Sick, Receipts for Invalid Foods and Beverages, Weights and Measures, Dose List, and a Full Glossary of Medical Terms and Nursing Treatment. By EMILY A. M. STONEY Superintendent of Training School for Nurses, Carney Hospital, South Boston, Massachusetts. London: The Scientific Press, Limited. Pp. 456. Price 7*s.* 6*d.*

"IN preparing the subject-matter of this volume, whose title-page clearly indicates its design, the author has attempted to explain, in popular language and in the shortest possible form, the entire range of private nursing as distinguished from hospital nursing, and to instruct the nurse how best to meet the various emergencies of medical and surgical cases when distant from medical or surgical aid, or when thrown on her own resources, studiously refraining, however, from advising the nurse to act upon her own responsibility or to assume personal treatment of the patient except under circumstances of great urgency."

This extract from the preface sufficiently indicates the scope and aim of the volume. The preface proceeds in a curiously complacent way to point out various excellencies in the work, with a self-confidence on the author's part which, we admit, is not entirely misplaced, for the book is the best of several good books on nursing which have recently reached us from America. It is brightly written, the subject being presented from the nurse's standpoint, and by one who takes a consistently high view of the position and duties of her calling. Though avowedly limited in its scope the book contains a very complete exposition of practical nursing in its various branches, including obstetric and gynæcological nursing. The instructions given are full of useful detail; indeed, we have not met with many books on the subject in which so few omissions can be pointed out; especially do we note the sensible way in which plain physiological reasons are given for the various modes of treatment enjoined, reasons so often withheld, and without a knowledge of which it is impossible for a nurse to work intelligently. The chapters on the Administration of Baths, Packs, and Douches, and those dealing with enemata and injections in general are particularly good in this respect. Throughout the book an admirably high standard of asepticism is advocated, the details given of the various antiseptic methods being most accurate and up-to-date. Errors, of course, there are, but they are not numerous. It is probably by a slip that the air is described on page 289 as being composed "mainly of oxygen and nitrogen, *there being more oxygen than nitrogen.*" On page 45 it is stated that "the Cheyne-Stokes respiration ..... is a fatal symptom"—a much too sweeping statement when thus unqualified. The composition of a nutrient enema is given on page 64 with ingredients amounting to from four ounces to six ounces. This is too large as a general rule, and no mention is made of the use of peptonising agents in this method of feeding. Full directions are given on page 271 for administering an enema to a young baby for ordinary constipation; but it is not pointed out that at this age the actual injection of fluid is seldom necessary, the insertion of the enema nozzle, a twist of soft paper, or the lubricated finger being generally all that is required. On page 276 the nurse is told to "snip" the frænum in a tongue-tied baby, no directions being given except the placing of a little sugar on the lower lip to cause the baby to put out its tongue. It is added that "no anæsthetic is required, neither is there any loss of blood." If nurses are to divide the frænum linguæ—an operation, in our opinion, better left to the surgeon—they should at least be taught the importance of keeping the scissors' point directed close to the jaw-bone rather than towards the base of the tongue, or they will find that hæmorrhage is by no means impossible, even in so simple an operation as this, if performed without due skill. And this is one of several instances in which, in spite of the disclaimer in the preface, the nurse is led beyond her province, and it is the only real fault we have to find with the book. The nurse is instructed, for example (p. 152), how to administer anæsthetics, and advised to use hypodermic injections of one-sixth of a grain of morphia, without medical direction, under a great variety of circumstances, including commencing appendicitis and acute scarlatinal nephritis. The author discusses the morphia question as an open one, and decides that the nurse is justified in initiating the treatment on her own responsibility. This is a doctrine which may perhaps have some justification in America, where it is possible that a nurse may have to work occasionally at a very great distance from medical advice, but it is one which we consider altogether untenable in England. A nurse should under no circumstances whatever administer morphia hypodermically except under orders. To allow her to do so is unfair both to herself, the patient, and the medical man; it invests her with a responsibility which she should in no wise be called upon to assume, and it is a definite infringement of that line which should distinctly divide the provinces of the physician and the nurse. The same remarks apply to the administration of anæsthetics by nurses.

More than twenty pages of the book are occupied by an exhaustive dose list, which, as it suggests prescribing, seems somewhat out of place, and there is a full and useful glossary of medical and nursing terms in which the only error we find is the definition of "pupil" as "the iris, or centre of the eye." The recipes for sick room cookery of all kinds are admirable and trustworthy. The book is handsomely got up, the type is excellent, and the illustrations are good. With due regard to the modification indicated above it will be a reliable text-book for nurses.

The Vertebrate Skeleton. By SIDNEY H. REYNOLDS, M.A. Cantab. Cambridge University Press. 1897. Pp. 527. Price 12*s.* 6*d.*

THIS work, which is one of the Cambridge Natural Science Manuals, should prove valuable alike to the beginner and to the more advanced student. It commences with an introductory account of the skeleton in general, in which the structure of the various exoskeletal tissues—such as claws, hair, teeth, horns and feathers—is described; then the methods of ossification are discussed; and afterwards the general development of the cranium and the rest of the endo-skeleton is briefly and very clearly described. The second chapter contains the classification which the author decides to adopt in the succeeding pages. Probably every worker at zoology would or could criticise every system of classification not his own; but the present one has at least the merit of showing the reader exactly what the author means, while it has also the advantage of indicating the relationship which various extinct animals bear to those at present inhabiting the Earth. The rest of the work describes the skeletal structures in the different divisions of vertebrata, beginning with amphioxus and balanoglossus, and ending with the primates, certain animals being wisely selected as types and their bones described in detail, it then only remains to point out how other animals in the class or order differ from them. A considerable number of references to recent literature is given in the form of footnotes; these, though undoubtedly valuable, might have been more representative.

The book is illustrated by 110 clear, straightforward

Digitized by Google

figures, each of which has the points of interest indicated by numerals which correspond to names under the illustration. It would be quite possible to get a very fair knowledge of comparative osteology from a study of the figures alone in this book The printing and paper are all that can be desired, while the author's style, always clear, is perhaps as attractive as the condensation of a large mass of osteological facts will allow. We feel sure that the book is well worth the attention of all who are interested in the subject.

LIBRARY TABLE.

The Administration of Nitrous Oxide and Oxygen for Dental Operations. By FREDERIC W. HEWITT, M.D. Cantab. London: Claudius Ash and Sons. Pp. 88. Illustrated.—After a brief *résumé* of the history of the employment of nitrous oxide gas, and of that body mixed with oxygen, the writer describes his apparatus and gives directions for the effective use of this mixture of gases. Hillischer, of Vienna, was the first to introduce the method in his well known pamphlets on "Schlafgas" as he called nitrous oxide and oxygen, and his experience of over ten years confirms his favourable opinion of this anæsthetic. Dr. Hewitt, however, found Hillischer's apparatus unsatisfactory, and with considerable ingenuity devised one of his own. He claims that by its use a more prolonged anæsthesia (forty-four seconds) can be obtained, all asphyxial symptoms can be abolished, and a safe and reliable anæsthetic for use in minor surgery obtained. He justly remarks that the mixture requires more experience for its use than does nitrous oxide, and the apparatus is more complicated and more liable to get out of order. The descriptions are clear and thoroughly practical, and should form a satisfactory guide to those who are interested in this branch of surgery.

Encyclopädisches Englisch-Deutsches und Deutsch-Englisches Wörterbuch. Zweiter Teil: Deutsch-Englisch. Bearbeitet von Professor Dr. DANIEL SANDERS. (*Encyclopædic English-German and German-English Dictionary.* Part II.: German-English. By Professor Dr. DANIEL SANDERS.) Berlin: Langenscheidtsche Verlagsbuchhandlung. London: H. Grevel and Co. New York: The International News Company. 1897.—This valuable and comprehensive dictionary is being published in parts, of which there will be about twenty-four, and from four to six will appear annually. Each part contains from 96 to 112 pages, and costs 1*s.* 6*d.* The German-English portion will occupy about 2500 pages, and will be completed in the year 1900. The English-German portion, by Professor Ed. Muret, has been brought out in the same way, and is now on the point of completion; the first half-volume extends from A to K, the second half-volume (L-Z) is promised for July, 1897; and these two together will contain about 2500 pages. The first part (A-Anbannen) of the German-English portion is before us; it shows that the work is carried out with conscientious thoroughness and is quite in accordance with the most advanced development of lexicography.

Report relating to the Registration of Births, Marriages and Deaths in the Province of Ontario for the year ending Dec. 31st, 1896. Printed by order of the Legislative Assembly of Ontario. Toronto: Warrick Brothers and Rutter. 1897. Pp. 36 and cxviii.—In the year 1895 the province of Ontaria contained 2,211,101 inhabitants; for each 1000 of this population the birth-rate during the same period was 18·8, the marriage-rate 6·3, and the death-rate 10 1. A copious and detailed summary of the registration returns is now published in a conveniently arranged volume which comprises upwards of 234 pages of tabular matter and will commend itself to those who are interested in the study of vital statistics. A new Registration Act which came into operation in May, 1896, is here printed in full.

La Nature et la Vie: Régénération de l'Homme par le Végétal. Par GABRIEL VIAUD. Paris: Charles Mendel. 1897. Pp. 255.—The author of this well-written book is a veterinary surgeon in a French artillery regiment, who has much to say on the physical advantages of a vegetarian diet as well as on the elevating influence of a fondness for flowers. The work consists of two essays, "Thérapeutique Végétarienne" and "Littérature Végétarienne," the first of which is of some medical interest, being an account of the author's experiments with a view to the medicinal administration of mineral tonics, such as iron, in the form of salads. For this purpose young plants of lettuce and endive were watered with a weak solution of tartrate of iron and potash, containing at first five grammes of the salt in four or five litres of water (= from seventy to ninety grains per gallon), but after a certain period about two or three times as much. Also when the fully-grown plants were taken up for use the cut ends of the stalks were immersed in the same ferruginous solution for twenty-four hours. M. Viaud states that plants treated in this way contain a large amount of iron which is not in the form of a definite chemical salt absorbed by capillarity, but is in actual organic combination with the vegetable tissues, and is therefore much more readily assimilated when the salad is eaten than any pharmaceutical preparation could be. With the same object he grew cress on a coarse cloth kept in contact with water contained in a large tub in which pieces of rusty iron were placed, some of the tartrate of potassium and iron being subsequently added. At a farm in Vienne in the east of France he found that cows and horses were greatly benefited by lucerne and clover which had been treated with a solution of sulphate of iron, phosphate of soda, and nitrate of lime.

Climbing in the British Isles: Wales and Ireland. By W. P. HASKETT SMITH, M.A., and H. C. HART. London and New York: Longmans, Green, and Co. Pp. 197. Price 3*s.* 6*d.*—Holiday-makers with mountaineering tastes will find this little volume an excellent companion on an excursion to Wales or Ireland. The authors, both of whom are members of the Alpine Club, have brought together in a compact narrative an extensive collection of practical information relative to mountain climbing in each of these countries. The ascent of steep rocks and dangerous enterprises upon cliffs have an especial charm for them; so it happens that the grassy hills of South Wales are dismissed with a brief notice, while, on the other hand, the Carnarvonshire mountains are described in much detail, forty pages being given to Snowdon alone. The section on Ireland is the work of Mr. Hart, who gives a survey of the whole country from the mountain-climber and cragsman's point of view. The highest summits in Ireland are found in Macgillicuddy's Reeks in County Kerry; Beenkeragh having an elevation of 3314 ft. Many views, both in Wales and Ireland, are given in the illustrations.

Black's Guide to Bournemouth and the New Forest Edited by A. R. HOPE MONCRIEFF. London: Adam and Charles Black. Pp. 72.—The descriptions of this picturesque and popular portion of the south coast are copious and well-selected. They include several places of interest at a distance of some miles from Bournemouth, and are amply illustrated with maps and plans.

The Fernley Observatory, Southport, Report for the year 1896. By JOSEPH BAXENDELL, F.R.Met.S. Printed for the Southport Corporation by Wm. Milne, Nevill-street.—The increased attention which is being paid to climatology gives special interest to this report, and the example of the borough of Southport in appointing a borough meteorologist might be followed with advantage. A like series of reports issued annually from all our watering places and balneological

Digitized by Google

resorts would prove of immense value to medical men in all parts of the kingdom.

The *Cyclist's Pocket Book and Useful Memoranda*, 1897. London: Archibald Constable & Co., Whitehall-gardens.—This is a little book for cyclists that will go into the breast pocket, containing useful information and memoranda, with a cyclist's almanack and telegraph code and an abstract of the law relating to horseless carriages. A few short pages are devoted to medical hints for purposes of first aid, which will be found useful in cases of slight accident or ailment. For the more severe forms, and for general instructions as to the safe and sensible use of the bicycle, riders should be guided solely by their medical advisers.

JOURNALS AND REVIEWS.

In the medical reports published by order of the Inspector-General of Customs in China for the half-year ended March 31st, 1896, are several important papers, besides that by Dr. J. Matignon on Typhus Fever, which we reserve for notice at greater length. In his report on the Health of Hankow Dr. J. D. Thomson reports two cases of death from heatstroke which occurred to workers in some iron-works. During 1894—Dr. Thomson's report is for the nineteen months ended Sept. 30th, 1895—enteric fever of a severe type prevailed during the summer and autumn. Out of sixteen cases treated in hospital there was one death. A hospital sister, aged sixty-seven years, was seized with acute cholera and only saved by saline injections into the cellular tissue. Dr. H. M. McCandliss, in his report on the Health of Hoihow for the year ending March 31st, 1896, mentions that in five months there were 3000 deaths from plague, the mortality being from 70 to 75 per cent.

The *Practitioner* for July, apart from the scientific interest of its contents, has a special value for ourselves because the "Hero of Medicine" for the month is Thomas Wakley, the Founder of THE LANCET, while a well-informed paper upon the duties of the medical man to the State takes as its text the Parliamentary achievement of the same reformer. Both articles to some extent owe their inspiration to Dr. Sprigge's recent volume, "The Life and Times of Thomas Wakley," concerning which book terms of compliment are used that cannot fail to be highly pleasing to the author, as they are to ourselves, under whose editorial supervision the work was issued serially. We have been much gratified by the generous appreciation of Thomas Wakley's services that has been manifested by the press and the public recently; and the straightforward testimony to the value of those services contained in the current *Practitioner* has touched us nearly because of its obvious emanation from well-informed pens. Mr. W. Rose has a paper in this issue on Early Colotomy in Malignant Disease of the Rectum in which he favours the iliac incision and complete division of the bowel. Dr. Litteljohn's instructive paper on Contagious Disease in a Poor-law School we notice at length in another column. There is also an amusing paper by a ship's surgeon upon the eccentricities of Quarantine before to the late Venice Conference.

The *Medical Magazine* for June has two exhaustive articles on the Progress of Medicine and Surgery during the past sixty years, the fifth instalment of Dr. W. Bruce's articles on Medical Reform, and a very admirable and practical paper by Mr. H. E. Counsell, F.R.C.S. Eng., upon Aseptic Surgery.

In the *Scottish Medical and Surgical Journal* for July one of the most interesting articles is a case of Simple Duodenal Ulcer, in which the symptoms pointed rather to its being a case of appendicitis; death followed in nineteen hours. The case occurred in the practice of Dr. G. M. Cullen. Another interesting paper is a digest of the details of some 300 cases of duodenal ulcer collected by the same practitioner. Dr. Graham Brown describes an ingenious modification of the pantograph for taking tracings of curved surfaces such as the thorax or cranium.

In the *Edinburgh Medical Journal* for July Dr. Byrom Bramwell commences a series of lectures on Aphasia, founded on the cases the details of which have recently appeared in our columns. Dr. Alexander Robertson gives some interesting examples of the use of Hydropathy in Practice, and Dr. Kanthack and Dr. H. M. Tickell contribute a paper upon the Etiology of Infective Endocarditis, which paper they modestly call "brief notes." As, however, it contains a fairly exhaustive analysis of eighty-four cases we think it deserves a larger name.

In the current number of the *Cornhill Magazine* Dr. E. T. Withington gives some curious details of mediæval trials of animals, insects, &c. The animal most frequently arraigned was the sow for the crime of eating babies, but as late as the eighteenth century a colony of ants was successfully exorcised as an alternative to legal proceedings in South America.

In the *Westminster Review* is a curious paper by Mr. H. J. Keene drawing a parallel between Byron and Napoleon. There have been many views of Waterloo, but to learn that it was not a battle is certainly the most startling theory we have come across.

The *Contemporary Review* contains a paper by Mr. R. H. Heath upon the similitude between Bunyan's "Holy War" and that orgie of mysticism the Anabaptist movement in Münster. Mysticism is a frame of mind always liable to excess, but mysticism unrestrained by authority or tradition is simple mania.

The current number of the *Leisure Hour* is full of interesting reading. "Puffs and Drugs" is an amusing article on the ways of the nostrum vendor, by Prebendary Harry Jones, and exposes some of the tricks of trade which are resorted to by a class of people who make a living out of the gullible public.

Sunday Hours still continues to maintain the standard of excellence with which it started a few months ago, and no more healthy and instructive magazine could be placed in the hands of girls and boys for Sunday reading.

The *Girls' Own Paper* and the *Sunday at Home* are also magazines which maintain their high tone of excellence.

New Inventions.

A WATER ANALYSIS CASE.

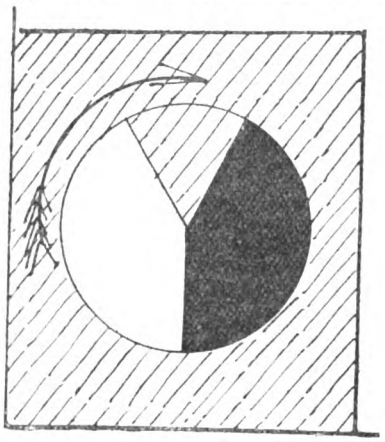
IN THE LANCET of Jan. 23rd, 1897, reference was made to a simple method of water analysis so devised that analytical operations could be carried out with a fair degree of accuracy upon the spot or at home without the need of special or complicated apparatus. This departure was due to Dr. Thresh, the medical officer of health of the county of Essex, and recent experimental trials in THE LANCET Laboratory enable us to say that the method places within the reach of medical officers of health, water engineers, and others a convenient, easy, and tolerably accurate means of sorting good waters from bad. All the apparatus and reagents required are contained in a mahogany case measuring ten by twelve inches and five inches deep. The case is now supplied complete, with printed forms for filling up the ascertained results, by Messrs. Burroughs, Wellcome and Co., Snow-hill-buildings,

Digitized by Google

E.C., for two guineas. The case comprises the following reagents:—Capsules of Nessler's reagent, soloids of silver nitrate each corresponding to two milligrammes of chlorine; soloids of potassium chromate; soloids of acid sulphate of sodium; soloids of potassium iodide and starch; soloids of zinc dust; soloids of soap each corresponding to 5 milligrammes of calcium carbonate; soloids of potassium ferrocyanide; and soloids of potassium permanganate, each corresponding to 0·10 milligramme of oxygen. The apparatus consists of a boiling flask of 100 cubic centimetres capacity with cork, a glass cylinder to contain 100 cubic centimetres and graduated in cubic centimetres, a small nickel evaporating dish, three glass cylinders of a capacity of 100 cubic centimetres and graduated at 70 cubic centimetres, stirring rods, tripod, a cleaning mop, spirit lamp, small glass funnel, filter paper, and a stoppered bottle to hold 120 cubic centimetres. The *modus operandi* and the measure of reliability of the results will be best understood from the data furnished below, first by employing the apparatus and the reagents in the case, and then by carrying out the analysis of the same water in the laboratory in the ordinary way. The water under examination was a specimen obtained from the new waterworks at Worthing. Analysis No. 1 gives the results obtained with the apparatus of the water analysis case, and Analysis No. 2 the results obtained by the ordinary methods of analysis in THE LANCET Laboratory.

RESULTS OF ANALYSIS 1.

Colour in 6 inch column ...	Bluish green.
Turbidity	Very slight, turbid on boiling.
Odour	None.
Residue on evaporation	Moderate.
Free ammonia	None.
Chlorine	1 soloid required, equal, say, to 2 grs. per gallon.
Equal to common salt	3·3 grains per gallon.
Nitrites	None.
Nitrates	Estimated just under 0·5 grain per gallon.
Hardness	Just 4 soloids required, equal to over 14 but under 18 grains per gallon.
Lead, zinc, iron, and copper	None.
Oxygen absorbed	Decidedly under 1 soloid (equal 1 grain).



RESULTS OF ANALYSIS 2.

Colour	Slight greenish tint.
Turbidity	Very slight, increased on boiling.
Odour	None.
Residue on evaporation	19 60 grains per gallon.
Free ammonia	None.
Chlorine	1·82 ,, ,,
Equal to common salt	3·00 ,, ,,
Nitrites	None.
Nitrates	0 35 ,, ,,
Hardness	16·5 ,, ,,
Lead, zinc, iron, and copper ...	None.
Oxygen absorbed	0 02 ,, ,,

These results fully establish the reliability of the simple method in affording a means of discriminating waters of bad, good, or indifferent character. The operations involved do not require much time to be spent on them, and they may be conveniently carried out at the source of supply. Medical officers of health have not, as a rule, the time or appointments to carry out the analysis of water at any length, in consequence of which they are led to recommend that an analysis should be made by a recognised official, a recommendation which is seldom carried into effect by the authorities advised. By the simple method described the medical officer is enabled to derive an opinion based upon the fairly reliable results obtained by himself at very little sacrifice of time and without much complicated apparatus being required. The introduction of the method is, therefore, important as adding very materially to the armamentarium of the sanitary officer. It should prove also of eminently useful service (as, for instance, in determining quickly the degree of hardness of waters) to water engineers and others concerned in providing a water-supply free from reproach.

AFTER IMAGE.

AMONG the exhibits at the last conversazione of the Royal Society was a piece of apparatus producing some very striking effects by means of after images. The exhibito was Mr. Shelford Bidwell, F.R.S., who has given much attention to phenomena of this class and who has succeeded in designing a simple and most beautiful mechanism for producing them. He uses a thin metal disc, originally circular in form, and of, perhaps, a foot in diameter, but from which a sector of about 60° is cut away. The front surface of the remainder of the disc is divided radially into two equal portions, one of which is made black and the other white. The disc is illuminated by a good light, and is caused to rotate in such a direction that the open sector is preceded by black and followed by white. The accompanying wood-cut shows the shape and direction of rotation as so defined.

If now a coloured object be placed behind this rotating disc and viewed intermittently through the open sector it will appear to assume a tint complementary to its actual hue. Thus, for example, a picture of a rose painted with a green flower and red leaves is seen correctly tinted as a pink blossom surrounded by green leaves. The significance of these very striking phenomena has been discussed by Mr. Bidwell in two papers which have been published in the Proceedings of the Royal Society.[1] That the after image, seen as it is upon a white disc as background, should exhibit colours complementary to those of the original picture is in no way surprising; that is, indeed, a familiar observation and susceptible of easy explanation. But what is less easy to understand is the fact that at a certain speed of rotation, varying slightly with various individuals, but lying generally between six and eight turns to the second, the after image so completely masters the primary impression that the eye is perfectly unconscious of the original object. Two considerations suggest themselves in this connexion. In the first place the white sector occupies a much larger angle of the disc than the sector cut away, so that it is possible that the duration of the after image is longer than that of the original stimulus, and in the next place the visible colours, more or less complementary, are distinctly paler than the hues of the original picture. It is quite possible that what is perceived is not the true complementary image any more than the true original image, but a blend of the two in which by reason of its longer duration or some other circumstance the hues of the complementary image prevail. The obvious paling of the tints tends to confirm this suggestion.

Even more interesting to the physiologist than the experiments exhibited at Burlington House are some described by Mr. Bidwell in his last communication to the Royal Society, in which black objects were submitted to examination by means of the rotating disc and red or green appeared as complementary hues to the black, according to the varying conditions of illumination and frequency of revolution. They are, no doubt, as Mr. Bidwell points out, susceptible of more or less complete explanation upon the Young-Helmholtz theory of vision, but the explanation is by no means simple, and leaves enough still obscure to stimulate the ingenuity of observers, whether in devising crucial experiments or elaborating theories.

THE LANCET.

LONDON: SATURDAY, JULY 10, 1897.

ON the occasion of the QUEEN'S Diamond Jubilee procession on June 22nd last our foreign visitors and all of us were greatly impressed with the self-government of the crowds of spectators in our streets—with the patience, good temper, and orderly behaviour of the masses of people who came out to do homage to a great Sovereign and a good, large-hearted woman. It was a striking phenomenon, and we had not to go far to seek for an explanation of it, for it was founded on mutual trust, sympathy, and goodwill, and on the recognition that all had a common purpose and were sharers in a spirit of common pride and interest in the celebration of events of which the pageant was but an outward sign, symbol, and token. All present were sufficiently intelligent and educated to share in one and the same community of feeling. This has not been the growth of a day, but the result of progressive development—of a slow but sure process of evolution in civilisation and freedom. Nothing of this kind exists in Eastern countries, and it would be well, we think, if people in this country would pause to consider the fact in connexion with the occurrences that have been recently taking place in India—at Poona and Calcutta. It is very easy to give these occurrences an exaggerated significance out of all proportion to their real importance, and it is difficult to dispel the fears of impulsive timid people who are always ready to discover the germs of another Indian Mutiny in every expression of discontent. But there is, happily, no evidence whatever to prove that the outrages and assassinations at Poona and the riots in a suburb of Calcutta are attributable to a common cause or connected with one another. The alleged, and probably the real, cause of the occurrences at Poona was connected with the measures adopted by the Government for dealing with the epidemic of bubonic plague; those at Chitpur and Calcutta were mainly attributable to a tumult among low-class Mahommedans, who made a pretext of an alleged desecration of the site of a mosque for creating a disturbance. Still, it cannot be denied that there are manifestations of a spirit of unrest in India at the present time sufficient to cause some anxiety.

Those who have resided in India for any time and are acquainted with the native population are perfectly well aware that the people generally are a patient, quiet, law-abiding, and, on the whole, contented people and well satisfied with our rule. There is no "public opinion" in the country. What pretends to be so is in no way representative of the mass of the people, but is commonly the outcome of a comparatively small, disaffected, noisy, and very cowardly class who have little respect for truth and a passion for strife and discord. The masses are very poor, very ignorant, and intensely conservative. They want, above all things, to be let alone, and they would sooner run the risk of disease and death than alter any of their customs or depart from their traditional beliefs and habits. They do not want to rule themselves and are unfit to do so, they are ignorant of all sanitary laws, and do not believe in their efficacy. The Government of India probably knows quite well what to do in cases of epidemic disease, but the difficulty is how to do it in the face of all the ignorance, popular prejudice, and poverty to be contended with. The effect of all this is more or less paralysing, of course; still, progress is made, but it must of necessity, under such circumstances, be very gradual and slow. The trust and confidence of the people have, as far as practicable, to be cultivated, but it is, of course, occasionally necessary to take prompt and decided steps to meet cases of emergency, and the support of the more enlightened, educated, and responsible classes in India is commonly with the Government on such occasions. The late epidemic of bubonic plague was indubitably an occasion of this kind. There are many people who think that had the more active and decided measures, which had to be ultimately followed, been adopted earlier, the spread and dimensions of the evil would have been greatly reduced. The difficulties of the Government of Bombay were obviously very great, and consideration for the feelings and prejudices of the people probably caused them to hesitate. They were compelled, however, in the general interest to adopt decided measures, and these have proved successful, as everybody foresaw they would. It has been urged that these measures were carried out in a needlessly harsh and cruel way, and allegations of gross misconduct on the part of the troops have been made, of which the recent outrages at Poona are said to be the natural outcome. It seems to us most mischievous and reprehensible for people in this country to bring charges of this kind against a Government engaged in stamping out a virulent epidemic without first of all making themselves thoroughly acquainted with the facts. India can never be governed properly in this way. The task is hard enough as it is, but it will be attended with insuperable difficulties if the British authorities and soldiers in that country are to be misrepresented and maligned by ill-informed and irresponsible politicians and faddists here. Systems of government are, no doubt, all the better for being exposed to the keen but healthy breeze of public criticism. It is to them what ventilation is to our houses and habitations, and we need not say that we hold no brief for the defence of the Indian Government or of the British Army in that country. Such attacks and criticism must be fair and just, however, if they are to have any wholesome effect and to avoid being positively injurious. It seems, however, far less likely that India will be taken from us by some foreign Power than that we shall lose it by our own ineptitude for its government through the application of measures and methods that are not adapted to it.

Lord GEORGE HAMILTON had no difficulty in carrying conviction to the minds of all reasonable men that the facts had been grossly misrepresented and exaggerated. He read in the House of Commons the full reply he had received from the Government of Bombay to the allegations that had been made, and

Digitized by Google

we need not trouble our readers with it. But we ask, Is it conceivable that, in carrying out absolutely necessary sanitary measures among a people altogether ignorant of all sanitary science, the authorities should have acted in the way they are accused of having done? Seeing that a number of female medical practitioners, nurses, native gentlemen, and others were present; that the work was carried out under the supervision of the Governor and General Officer commanding, the Surgeon-General, and numerous medical and other officers; and that the troops had been expressly cautioned to act with every consideration, it is incredible that preventive measures were carried out with an absolute disregard for decency and for the caste and religious feelings of the natives. The soldiers forming the search parties bravely undertook a dangerous and most disagreeable duty, and discharged it, we make no doubt, with all proper care and delicacy; all independent testimony is to that effect, and they could not, indeed, have done otherwise under the circumstances in which they were placed.

THE Lumleian Lectures on Some Problems in Connexion with Aphasia and other Speech Defects, recently delivered before the Royal College of Physicians of London by Dr. CHARLTON BASTIAN and published in our columns,[1] are worthy of the most careful attention on the part of everyone who is interested in the more abstruse problems of nervous disease or in the physical aspects of psychological processes. Dr. BASTIAN is to be congratulated upon the graphic manner in which he has re-enunciated the views on this subject which are so closely associated with his name and upon the striking array of evidence in favour of his views which he has marshalled before his readers. Those views as to the nature of the functions of the so-called "motor areas" of the cortex are well known. According to Dr. BASTIAN these are to be regarded as not really motor but as "sensory centres of kinæsthetic type by means of which movements are guided," the true motor centres being situated in the medulla oblongata and the spinal cord. In a similar way he believes that there are two centres, also of kinæsthetic type, one related to articulatory processes, a glosso-kinæsthetic centre, and the other in relation to the movements connected with writing, a cheiro-kinæsthetic centre. Besides these sensory centres there are also an auditory word centre and a visual word centre, devoted to the reception and consequently to the revival in thought of impressions of words. The existence of those is generally recognised, although the position in the cortex which they respectively occupy is still a matter of at least some uncertainty. But with reference to the two kinæsthetic centres already alluded to, Dr. BASTIAN thinks there is less doubt, and he himself believes that the part of the cortex so long and closely associated with the name of BROCA—the posterior part or foot of the third frontal and the inferior part of the ascending frontal convolutions—is the part alluded to as the glosso-kinæsthetic centre, while the cheiro-kinæsthetic centre is by no means so definite, although it is probably to be looked for in the vicinity of the posterior part of the second frontal gyrus. Besides these four centres—the auditory and visual word centres and the glosso- and cheiro-kinæsthetic centres—there must also be supposed to be fibres connecting these, and accordingly lesions relating to speech defects are to be looked for in four different situations—in the word centres themselves, in the commissures connecting those, in the fibres connecting the two kinæsthetic centres with their related motor centres, and in the motor centres themselves. Such is the strong and apparently sufficient foundation upon which the lecturer has constructed a system capable, he believes, of explaining cases of defect of speech.

One very much disputed question amongst writers and thinkers on disorders of speech is the question whether conception or ideation takes place in a centre altogether apart from that related to perception. The view that such was the case was first enunciated by Sir W. H. BROADBENT, who distinguished in the process supposed by Dr. BASTIAN to be carried on in the perceptive centres already alluded to two stages—a primary one, in which the external cause of a given set of sensations is recognised in its simple form, colour, hardness, &c., and another stage in which there is a higher degree of elaboration and a conception or idea of an object as a whole is obtained. This centre for concept was also called the "naming centre," and a related higher centre was postulated—a "propositionising centre"— in which words other than names were supposed to be registered, and in which sentences were supposed to be formulated preparatory to their utterance through the instrumentality of Broca's convolution. This view is, of course, entirely different from Dr. BASTIAN'S, according to whom an impression of an object on reaching the cerebral hemispheres, although it strikes first on the related perception centre, immediately radiates so as to impinge upon functionally related structures, all this taking place so rapidly that the several excitations are practically simultaneous, and so the combined effects are fused into one single perceptive act. Thus, Dr. BASTIAN and those who agree with him regard the work which Sir W. BROADBENT and his supporters suppose to be done in the "naming" centre as effected by the simultaneous activity of the different perceptive centres and of certain annexes. The lecturer further fails to find any clinical phenomena rendering the existence of such a centre necessary.

A certain degree of reconcilement between these conflicting views seems possible in Dr. BASTIAN'S association with his perceptive centres of "certain annexes." FLECHSIG has directed attention to certain areas in the cortex which differ from sensory areas, and he assumes that these subserve the higher mental functions. He terms them "association areas," and, as Dr. BASTIAN points out, they are really the areas which long ago were indicated by Sir W. BROADBENT as the probable seat of the more purely intellectual operations, and presumably, therefore, the areas in which was to be placed his propositionising centre. All recent knowledge of cerebral functions has tended to show that anything like hard-and-fast lines circumscribing any particular centre are at least not the rule, and even granting that combined sensory areas together with the annexes are accustomed to be thrown into functional activity more or less simultaneously, and that the processes of perception and conception and the

[1] THE LANCET, April 3rd, 10th, and 24th, and May 1st, 1897.

Digitized by Google

revival of linguistic symbols are inseparable in every relation, yet it may be thought by some that it conduces to clearness to associate this higher function with something to which the name "centre" is applied for convenience only.

Having thus devoted the first lecture to a full setting out of the physiological first principles in reference to speech defects, Dr. BASTIAN proceeds to discuss the various defects that are met with in the speech functions, dealing first with the structural defects met with in the glosso- and cheiro-kinæsthetic centres. He brings forward much evidence to show that, contrary to the views of DÉJERINE and others, agraphia is not produced by any isolated lesion of Broca's centre, a contention incidentally demonstrating the necessity for the recognition of a cheiro-kinæsthetic centre The various defects met with in the auditory and visual centres are next dealt with, and much fresh light is thrown upon the problems discussed by the numerous cases which are quoted in this connexion. The nomenclature at present in use is also criticised in several particulars.

It is a curious coincidence that almost simultaneously with the publication of these lectures there should have been appearing in our columns, from the pen of Dr. BYROM BRAMWELL, detailed accounts of one of the most wonderful series of cases of aphasia ever published. These cases cannot fail to have impressed all who read them on account of the extreme care with which they had been observed clinically, and also on account of the importance given to them by the careful record of the pathological condition which was found in those examined. It is also noteworthy that one of Dr. BRAMWELL'S professed objects in publishing those cases was to support the view that the right hemisphere must be regarded as taking an important part in relation to the mechanism of speech, a view also strongly insisted upon in Dr. BASTIAN'S lectures. It is further of interest that in at least two of his cases Dr. BRAMWELL finds reason for arriving independently at the view which Dr. BASTIAN has so clearly enunciated—that complete destruction of Broca's convolution does not necessarily produce agraphia.

In studying Dr. BASTIAN'S lectures and Dr. BRAMWELL'S clinical cases, with the conclusions he deduces from them, the reader cannot but be struck with the admirable lucidity which characterises both contributions. The lectures are necessarily to some extent controversial; but the facts are presented with the utmost fairness, and the views enunciated in them will, we believe, long remain as an authoritative exposition of Dr. BASTIAN'S theories. Dr. BRAMWELL'S series of accurately observed and carefully recorded clinical and pathological facts forms, we are glad to know, only a preliminary contribution to the fuller and more systematic discussion of a subject on which his views will be awaited with interest and received with consideration.

THE PRINCE OF WALES spoke with much sense and moderation of his Hospital Fund for London on the occasion of the dinner of the Master and Elder Brethren of the Trinity House on Saturday last. He has the faculty of condensing into a few words the gist of a question. His words on this subject were, indeed, so few and so well ordered that we may with advantage bring them to the memory of our readers:—

"In my efforts for the hospitals I trust that in time I may be successful. The work does not progress as fast as we could wish; but we must have patience. I hope that the hospitals will be set on a firm basis, and that the public will come to feel that the money spent on them is not spent in vain."

We recognise in these words proof that the PRINCE realises that he has undertaken no easy task and that the public will have to be convinced that the money given to him for this purpose will be well expended. And in this sober judgment of the case we see the best security of the ultimate success of his labours. His Royal Highness will have at any rate this consolation—that if he does not succeed nobody else is likely to do so, and that even if he does not get the full sum which he proposed to raise he will have conferred a very great favour on institutions and earned the gratitude of all who are responsible for their maintenance. The Jubilee year is little more than half gone, and yet large sums still continue to flow into the Fund in a way to justify that fine note of faith in his speech that eventually he would succeed. He began this movement with a deep desire to engage large numbers in the support of hospitals and on the theory that small sums from them would solve the problem. He estimated that the deficiency in the ordinary income of hospitals as compared with their ordinary expenditure — amounting to £70,000—would be met by exciting the interest of the many who do not give and yet who could afford to give at least 10*s.* a year to hospitals. He explained that there were three reasons why this large number of persons—representing at least 225,000 metropolitan households—did not subscribe: firstly, the difficulty of choosing among so many deserving objects; secondly, the lack of any definite opportunity for giving annual subscriptions to the cause as a whole; and thirdly, the feeling that small sums were scarcely worth contributing. The PRINCE excluded indifference or want of sympathy as possible explanations why so many who could afford to subscribe did not do so, and we have no desire to be less charitable in our own theory. We shall look anxiously to the remaining weeks of this eventful year for the confirmation of the PRINCE'S theory that there are 225,000 households which only need the suggestion and the opportunity to take their hitherto neglected share in maintaining institutions which alleviate pain and cure disease among classes that are too poor to provide the necessary skill for themselves. There still remain the rich in this metropolis, those who can find an opportunity of contributing to this cause whenever they please. It is not only those of comparatively small means who have failed to subscribe to hospitals, but the rich. Many rich men either do not subscribe at all or do so in a half-hearted way that does more harm than good. The only doubt we have about the original letter of His Royal Highness is the prominence given in it to the subscription of small sums "from a shilling per annum and upwards." The object no doubt was to encourage the humblest to do what they could. But, after all, the maintenance of our hospitals has always chiefly depended on the rich or the comparatively rich, who derive immense indirect benefits from hospitals as places where medical and surgical skill is perfected. We live in an age

Digitized by Google

when an ever-increasing number of men accumulate wealth beyond their need or that of their families. Splendid acts of generosity testify that the possession of such wealth is often consistent with sympathy for others who are lame and ill and in much need of help. The endowment of hospitals is the most direct way of showing such sympathy, and we cannot doubt that before this memorable year is ended the patience and labours of the PRINCE OF WALES and his colleagues will be rewarded by rich men casting into the treasury sums that will raise this capital Fund to £500,000 at least. The PRINCE'S recent speech and the composition of the Committee lead us to hope that the money so raised will be well spent. We are sure there is much in this. The PRINCE has ably refuted the miserable attempt to associate hospitals with acts of cruelty to the lower animals, which, in truth, largely benefit by every advance in medical science. He will do equal service in using his endeavours to convince the public that the money they give to him for this Fund will be spent on those who need it, and that any proved abuses of hospital charity will be regarded as demerits in the hospitals which permit them.

Annotations.

"Ne quid nimis."

THE HEALTH OF THE QUEEN

WE are glad to be able to state, on excellent authority, that certain rumours to which publicity was given last week with reference to Her Majesty's eyesight were grossly exaggerated. It is a fact that for some years her eyesight has been affected owing to changes incidental to her advanced age, but, although in the nature of things this condition may be slowly progressive, there is no truth in the statement that it is rapidly becoming worse. The deterioration of her vision naturally causes the Queen some inconvenience, but not to the extent of interfering with her ordinary course of life or of preventing her from discharging her multifarious and onerous duties. Her Majesty's health is, for a lady of her age, perfectly satisfactory. Indeed, there are probably but few ladies contemporary with her who could have borne so well the fatigue and strain of the recent Jubilee celebrations.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE total sum collected for the Metropolitan Hospital Sunday Fund now amounts to £31,000, including a donation of £500 from Sir Savile Crossley, the most regular and generous supporter of the Fund. This sum does not compare favourably with the amount collected last year at the corresponding date, but it is yet too early to make real comparisons, as many of the collections have not been made. The middle Sunday in June is usually chosen for the collection of the Fund, as being most convenient for the larger number of churches and chapels in the metropolis, but unfortunately this year the date clashed with the Sunday set apart for the special service in commemoration of Her Majesty's Diamond Jubilee. Special efforts, too, are being made this year to increase the subscriptions for the Clergy Sustentation Fund, and the day appointed for the collection of this latter fund also unfortunately fell upon the same date. Many of the churches have not yet had their Hospital Sunday Fund collection, the whole of the deanery of Fulham, for example, holding it as a matter of Church discipline to postpone their collection till later in the year. Among the legacies which have recently been bequeathed to the Fund is the munificent bequest of the late Mr. William Vokins, of Hove. In his will he bequeaths the sum of £15,000 upon trust, to be transferred at the death of his wife to the president and treasurer for the time being of the Metropolitan Hospital Sunday Fund, out of any £2 15*s.* per cent. Consolidated Stock standing in his name at the time of his death.

EXPOSING A SCARLET FEVER PATIENT.

A MAN named Thomas and his wife were on June 28th summoned at the Ystrad police-court for exposing their daughter while suffering from scarlet fever. The case was notified by the medical attendant, Mr. Evan Jones, of Pentre, on May 22nd, and on June 15th the sanitary inspector found the child out in the street. Mr. Evan Jones is reported as having said in evidence that by June 15th the infection was over. We suppose that the rash was out when Mr. Jones notified the case, so he must have considered that the child became free from infection in the space of twenty-four or at the most twenty-five days, a period, in our opinion, a great deal too short. No scarlet fever patient should be considered free from infection until the expiration of at least forty-two days from the appearance of the rash, and the medical officer of health, Mr. Herbert Jones, urged this point in court. The stipendiary, however, is reported as saying: "Dr. Jones has given us an instance of a case of infection having ceased in four weeks, so there was no danger." After this the case was dismissed. We see that according to Mr. Herbert Jones's last report, dated June 16th, 1897, the mortality for the fourteen years, 1882–1895, per 1,000,000 from scarlet fever was for England and Wales 267, but for the district of Ystradyfodwg 608, and if from three to four weeks is to be generally considered a sufficient period for isolation we are not surprised thereat.

THE ILL-HEALTH OF MOLIÈRE AND ITS CAUSE.

THE mysterious Boulanger de Chalussay, author of the libellous "Élomire Hypochondre, ou les Médecins Vengés"—who is described by Dr. A. M. Brown in his recently published work[1] as "a personage little known, but possessing no mean talent as a writer, and dangerous as an assailant on his own account or as a mercenary in a literary plot, where a rival's character and reputation were at stake"—endeavoured to brand the great French dramatist as a prating hypochondriac; psychologically, morally, and physically repulsive; a corrupter of morals and a buffoon, who regarded his medical advisers as assassins aggravating his malady by their vengeful treatment when as a patient they had him in their power; but after an exhaustive study of his theme Dr. Brown has come to the conclusion that in reality Molière was a victim of chronic phthisis. The passage in which this opinion is expressed runs as follows:[2] "The nature of the malady, which for years he had been nursing like a wolf within his breast, is far too strongly marked to leave a doubt upon our minds. The condition in which some profess to see thoracic aneurysm or cardiac disease, is much more easily explained; in his case these terms have more attraction than reality to recommend them. Rare diseases are not reserved for rarest men—here nature is impartial. Molière was an ordinary *poitrinaire*, the victim of that malady which the statistics of mortality have vulgarised. In every allusion, personal or narrated, respecting his health and sufferings we can trace a faithful record of a chronic ulceration of the lungs, continually masked by ailments peculiar to his high-wrought mind and constitution

[1] Molière and His Medical Associations. London: The Cotton Press, 1897. [2] Ibid., p. 200.

Digitized by Google

morbidly affected, destructive processes internally at work, and easily misread. To his worshippers it is the genius struggling with mental affliction, rather than the mortal suffering from bodily disease, that shows throughout the melancholy history of his illness. The characteristic cough, emaciation, constitutional debility, and occasional pulmonary hæmorrhage, present the veritable portraiture of those organic ravages, indefinitely prolonged, which receive the name of phthisis. It is rarely that we see that amount of constitutional resistance which the great comedian's case exhibits; the all unequal contest between life and death generally terminates much sooner, but, terminate when it may, the victory is never doubtful—the patient must finally succumb." Dr. Brown is no doubt correct in his views regarding the disease from which Molière suffered, and unquestionably he has thrown considerable light upon the inner life of the poet and the motives that actuated him in his raids against the medical profession. Whatever the cause may have been that prompted Chalussay to pen his ignoble satire, it is satisfactory to find that the Faculty did not consider itself honoured by his service, but, on the contrary, cordially disapproved of the libeller's caricature, which was universally thought to display animus as virulent as it was merciless.

MEDICAL SERVICE IN BRITISH CENTRAL AFRICA.

IT is generally allowed to be no empty boast that the Briton makes the best coloniser, but even if this is so it is no reason for wasting our material and it would seem that in British Central Africa at least we do not do as much as we might to avoid a sacrifice of valuable lives. Tropical diseases run so rapid a course that prompt treatment is needed if any good is to be done, and this means the presence of a medical man. The protectorate in question is about the size of England and Wales, has a population of 850,000, of whom some 600 are Europeans or subjects of British India. The number of medical men is only four, while in the German sphere, which is smaller than our own, there are no less than eighteen. During the year 1897 seven officials and sundry missionaries have died from hæmaturic fever and there have been seven or eight fatal cases of ordinary malarial fever. Of course, it cannot be said that these lives would have been saved had the patients been promptly attended to, but it would, at any rate, have given them a better chance. We do not know how much of the blame to apportion to the Imperial Government and how much to the British South Africa Company, who are the two governing bodies of the district, but in our opinion the supply of medical men should be at least trebled. It would seem that the deadly Crimean traditions of getting glory cheaply, or apparently so, for it is very dear in the long run, still hold good in many a department. We are ready enough to spend money on fads; let us give a little of it to life-saving.

WOOL-SORTERS' DISEASE AND ITS PREVENTION.

AN inquest recently held at Queensbury upon a man who died from wool-sorters' disease, and the proposed new regulations for the carrying on of that trade, have been the text of a correspondence and a leading article in the Bradford press. Shortly, the matter seems to stand as follows. The wool is sorted upon wire "hurdles," and underneath these is a tube, down which a current of air is driven by means of a fan. The minimum amount of air passing should be, according to the Government suggestion, 25 cubic feet per minute, while the operatives themselves wish for 75 cubic feet. It is also allowed that many firms have fans which give a great deal more than the Government minimum. But, as Dr. J. H. Bell pointed out in the *Bradford Observer* of July 1st, even supposing the dust and germs are removed from the neighbourhood of the sorter a certain amount is distributed broadcast, and the rest which falls into the receptacle has to be removed, a process which may be fatal to him who has to remove it. Dr. Bell suggests that all wool, hair, and skins should be disinfected at the port of entry. In our issue of May 22nd, 1897, in commenting upon a death from anthrax at Bradford, we said that the right thing to do was to disinfect the suspected goods before opening them. It is surely worth while to make some experiments upon this question. Anthrax is so deadly a disease, the vitality of the bacillus is so lasting under ordinary circumstances, and the loss to agriculturalists from its prevalence is so considerable, that it would seem to be the height of folly to leave any means untried which offer a way of escape, for even if the experiment failed the loss of a few bales of wool and of sundry hides would not ruin the Treasury when it was called upon to pay for them.

THE TREATMENT OF PERFORATION IN TYPHOID FEVER BY LAPAROTOMY.

AN important communication on this subject has recently been made to the Johns Hopkins Medical Society[1] by Dr. Finney. Laparotomy has now been performed in 47 cases with 13 recoveries. The best time for operating is as soon as the patient has recovered from the shock attending the perforation. This is usually in a few hours. Dr. Finney first examines the ileum and sutures any suspicious-looking patches. He removes the appendix if at all abnormal. Excision of the edges of the perforation is unnecessary. Should the intestine be in such a condition as to make suture impossible the loop may be pulled out and left until the patient has recovered from the fever. The peritoneum should be thoroughly cleansed by wiping. The small intestines may be irrigated, having been pulled outside the abdomen, but the abdominal cavity should not be irrigated if the inflammation does not involve the whole peritoneum for fear of spreading the infection. The worst or sutured coil is placed next the abdominal wound and packed with strips of gauze to ensure good drainage, for which a small opening is left. The necropsies show that healing was always taking place. Death usually resulted from septic absorption, but the records show some other complications—intestinal obstruction, a second perforation, or defective drainage of an abscess. The diagnosis of perforation is often a matter of difficulty; in 8 of the cases it was wrong. Dr. Finney places most reliance upon severe continued abdominal pain with nausea and vomiting and on a new sign—marked increase in the number of leucocytes. During typhoid fever there is no leucocytosis, but it occurs immediately after a perforation. Thus in 3 cases the numbers before and after were 8300 and 24,000, 6500 and 10,600, 3000 and 16,400. Another recent publication, by Dr. Francis R. Gairdner, in which the subject is treated from a different point of view, is also valuable.[2] He analyses the reports of 47 fatal cases of typhoid peritonitis which occurred in the Belvidere Fever Hospital, and compares them with published cases in which operation has been successful. By this ingenious method he obtains evidence of the success likely to attend laparotomy in general. He divides the cases into four classes. The first, the very favourable, contains 9 cases (19·1 per cent.). Here the perforation occurred in a quiescent stage of the disease or in the course of a mild attack, and the necropsy showed very slight affection of the gut. In many the perforated ulcer was the only considerable one present, and in all it was surrounded by sound gut. The second class, cases not quite so favourable, but none less favourable than successful cases already published, contains 14 cases (29·8 per cent.). The third, unfavourable, consists of 9 cases (19·1

[1] Bulletin, May, 1897.
[2] Glasgow Medical Journal, February, 1897.

Digitized by Google

per cent.). Many of these, however, would be submitted to operation if van Hook's dictum, "the only contra-indication is a moribund condition of the patient," were acted on. The fourth, altogether unfavourable cases, contains 9 (19·1 per cent.). There remain 6 cases in which peritonitis was not due to intestinal perforation. As these cannot usually be distinguished during life from cases of perforation they would, if operation become the practice, be submitted to it. But this would probably be beneficial in many. In 23, or nearly half the cases, the disease was in full activity at the onset of the peritonitis, while in the remaining 24 convalescence was nearly or quite reached. The duration of life after the onset of the peritonitis was in 3 cases less than 24 hours—viz., 8 12, and 18; and in 7 less than 36 hours. Thus all but 10 lived for at least 36 hours. Only 10 lived longer than 48 hours, and only 3 longer than 3 days—viz., 3½, 5, and 18. In the last two the peritonitis was not due to perforation. The analysis of the symptoms is valuable, showing the deviations which may occur from the typical condition. The mode of onset was usually sudden, but in 12 it was gradual. Of 39 cases the temperature was considerably raised after the onset of the peritonitis, in 22 either immediately or early, and in 8 it was lowered. The pulse was invariably quickened, though sometimes in the early stages not very much so. Pain was an initial symptom in 26 of 42 cases; it was absent throughout or very slight in about 8. Vomiting and hiccough were prominent in 14, but occurred at the onset in only 2. Meteorism occurred in about half the cases. As perforation is almost invariably fatal under medical treatment we consider that the success so far attained, though moderate (it will probably be greater in the future), should prevent the question of laparotomy being regarded any longer as *sub judice*. Every case should be given the chance afforded by operation where the general condition does not absolutely contra-indicate it.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE introduction of voting papers which can be sent by post for the election of members of the Council has completely changed the aspect of election day at the Royal College of Surgeons of England. Time was when on this day Fellows gathered from all parts of the kingdom, and nearly every Fellow in London recorded his vote. It formed a very pleasant occasion for renewing old friendships, for Fellows met there who did not see each other at any other time during the year; but though at the conclusion of the ballot the library was almost filled with Fellows anxious to hear the result of the poll, yet the total number of voters was not large, as so many were unable to be present. Nine years ago voting papers were introduced, and very soon the effect on the personal attendance of Fellows was seen; the numbers of those who came to the College to vote steadily diminished, but voting papers had to be asked for, and this restricted their use. Three years ago the plan of sending voting papers to all Fellows was commenced, and immediately the numbers of non-personal votes almost doubled, surpassing slightly even the numbers of the present year, when 607 voting papers were received by post. As the votes by proxy increased the personal votes fell off; 1894 was the last occasion when they exceeded 100, and this year they amounted only to 46. The chief effect of voting by post has been to increase the influence of provincial Fellows at the elections. The result is good, and there is no chance of a return to the ancient method of voting; it is, indeed, almost a question whether it will not be necessary to abolish personal voting altogether, as every year there is a greater difficulty in obtaining a quorum. At the election held last week the President had to wait ten minutes before there were six Fellows present, apart from members of the Council, so that he might declare the opening of the election. The results of the recent election may be considered as, on the whole, not unsatisfactory. We are glad to see that Mr. Howse was re-elected. Dr. Ward Cousins was re-elected also, and we may attribute this in part at least, to the very general, and very natural, disinclination which exists to decline to re-appoint retiring members of the Council who are applying for re-election. Mr. Edmund Owen headed the poll with 323 votes, thanks chiefly to the very large number of plumpers, 28 in all, which he received. No other candidate received many plumpers except Sir William Dalby, who had 10. Mr. Rickman Godlee came next to Mr. Owen with 312 votes, Mr. Howse followed with 307, and Mr. Watson Cheyne and Dr. Ward Cousins completed the number of successful candidates with 290, and 259 votes respectively. Mr. Bennett May and Mr. Morgan received each 236 votes, and Mr. Clement Lucas had 225. None of the other three candidates received more than 200 votes. We may express the hope that at the next election Mr. May, Mr. Morgan, and Mr. Lucas will again stand, and that the result of that election will bring them success. All the elected candidates may be regarded as valuable additions to the Council; how they will vote in the interesting questions of College politics time alone can show; but we may venture to hope that none of them will in any way retard, but rather help on, the progress of the College in the performance of the important duties with which it is intrusted.

THE PLAGUE IN BOMBAY.

WE have received a copy of the proceedings of the monthly meeting of the Bombay Medical and Physical Society held in May last, together with some voluminous charts showing the meteorological conditions that prevailed during the late epidemic of bubonic fever in the city and island of Bombay, and the mortality caused by the disease from September to March last, to which we have already adverted. The papers read before the society were upon the Clinical Types of Plague with Urinalysis, by Surgeon-Captain J. G. Hojel; Remarks on the Pathology of Plague, by Surgeon-Captain B. H. F. Leumann; and an Outline of Symptoms of Plague, by Surgeon-Major W. R. Lyons, M.D. The papers are valuable because hey embody the observations and results of those who have so recently had a practical experience of the disease, and the charts will form a useful record of the epidemic. The deaths from plague in September, October, and November were relatively few. These increased in December, and went on increasing greatly in January and February, in which month the epidemic was at its maximum, and began to decline in March. We may add that according to the latest telegraphic despatch from the Governor of Bombay the deaths from plague last week in Bombay city were only twelve, and no cases of, or deaths from, plague had occurred in the city of Poona. The mortality in all the affected areas was also steadily decreasing.

PSEUDO-BULBAR PARALYSIS IN CHILDHOOD.

IN a recent issue of the *Deutsche Zeitschrift für Nervenheilkunde* Dr. Brauer, of Heidelberg, has published the case of a girl, aged fourteen years, who had an illness characterised by fever and muscular pains, and after a few days was found to have symmetrical affection of the tongue and lips, with difficulty in articulation and in swallowing and slight paralysis of the right side. There was also afterwards interference with the development of the right arm. On examination about a year after the onset of the illness the skull was found to be normal, there was a symmetrical affection of the orbicularis oris, of the depressors of the lower lip, of the levatores menti, the pterygoids, the tongue, and

Digitized by Google

the palate. There was, however, no atrophy of these muscles, but the tongue, which was not well developed, was not moved in speaking. There were no fibrillary contractions, no electrical changes in the muscles, and no sensory impairment. The palate was paralysed, the palatal reflex lost, the jaw-jerk increased, the speech almost unintelligible, and the intonation distinctly nasal. The right arm was shorter and generally smaller than the left, there was slight weakness of the peroneal muscles of the right leg, and increased reflexes also on this side. The good condition of the muscles, the absence of fibrillary twitchings, the presence of the reflexes and the absence of electrical changes all speak in favour of there not being any nuclear lesion, and Dr. Brauer regards the condition as resulting from a supra-nuclear lesion, apparently the result of acute encephalitis.

CAMBRIDGE GRADUATES' MEDICAL CLUB.

THE annual meeting and dinner of this club, on Tuesday, July 6th, at Limmer's Hotel, Conduit-street, W., was attended by members and their guests to the number of fifty-nine. Dr. Howship Dickinson was elected to the office of president in the room of the late Sir George Murray Humphry, and occupied the chair at the dinner. After giving the loyal toasts of "The Queen" and "The Prince of Wales," he reviewed the chief events of the year in connexion with the Medical School of Cambridge. The death of Sir G. M. Humphry, the appointment of Mr. Joseph Griffiths as reader in surgery, of Professor A. A. Kanthack to be deputy professor of pathology, and the fact that in the person of Dr. Alexander Hill, Master of Downing, the University of Cambridge is for the first time in history under the rule of a medical vice-chancellor, were all alluded to in graceful terms. "The Guests" was proposed by Dr. Norman Moore in a speech characteristically full of humour and curious knowledge—a speech which brought out responses from Sir Samuel Wilks, Professor R. C. Jebb, Sir Joseph Fayrer, and Sir George Scott Robertson. The health of the chairman was eloquently given by Mr. Herbert Page.

CONGENITAL AND HEREDITARY OPHTHALMOPLEGIA.

IN a recent number of the *Revue Médicale de la Suisse Romande* Dr. Gourzein describes a family in which this peculiarity occurred. The paper is abstracted in the last number of the *Neurologisches Centralblatt*. The peculiarity occurred in the father of the family and in five sons, while the three daughters were unaffected. It was ascertained from the father that his mother had had the same affection and a sister had convergent strabismus. Examination of the father revealed almost complete ptosis, so that in order to see he had to throw the head back. There was complete inability to move the eyeball, but accommodation and the light reflex were present and the discs and fundi were normal. There was rotatory nystagmus, but no other affection of the nervous system. A similar condition was found in the eldest boy, aged twelve years, and in the second, aged nine and a half years, although in the latter there was retained some movement of the external and internal recti. The third child, a boy who died at the age of eight months, suffered in exactly the same way. The remaining two boys, aged respectively four years and eight months, presented exactly the same condition, while the girls were all normal. With the exception of the hereditary tendency no distinct etiological factor could be discovered. There was no specific taint or any form of toxic condition so far as could be ascertained. Dr. Gourzein believes that these cases of congenital ophthalmoplegia differ from the ordinary form due to nuclear degeneration in the fact that the ptosis is much more marked, that nystagmus is present, and that a greater or less degree of amblyopia co-exists, and he regards the condition as a purely muscular affection.

ROYAL COMMISSION ON TUBERCULOSIS.

MEETINGS of this Commission were held at 7, Whitehall-place, on June 30th and July 1st and 2nd, the Right Hon. Sir Herbert Maxwell, M.P., being in the chair. The other Commissioners present were Sir Richard Thorne Thorne, K.C.B., F.R.S., Professor Brown, C.B., Mr. Shirley F. Murphy, Mr. Cooke-Trench, and Mr. John Speir. Evidence was heard from Mr. C. Stephenson, F.R.C.V.S., representing the Royal Agricultural Society, Veterinary Inspector of the city of Newcastle and county of Northumberland, as to the extent of the disease in his district and the necessity for uniformity in any legislation so as to cover every channel by which the disease may be conveyed; from Mr. Samuel Rowlandson and Mr. Christopher Middleton, both representing the Central Chamber of Agriculture, the former also the Royal Agricultural Society; from Mr. Sessions, F.R.C.V.S., and Mr. Hunting, F.R.C.V.S.; from Sir T. D. Gibson-Carmichael, M.P., and Mr. Dobbie, representing the Scottish Chamber of Agriculture, the former of whom gave details as to the results of testing with tuberculin his Castle Craig herd.

RIVER POLLUTION AND WATER-SUPPLY.

THE following state of affairs may possibly account for the discrepancy that frequently exists between private analyses and the published reports of the water companies. Sunbury-on-Thames, with the sylvan surroundings that are still spared by the utilitarian hand of the water companies, is well known as a health resort or summer home to many a jaded City man. In the forty or fifty houses, the gardens of which extend to the river, a numerous colony annually congregates. These gardens are small and are more or less honeycombed by cesspools, there being two or three in each, many only a few feet from the river. These cesspools are apparently unprovided with any overflow, and not only do they receive the contents of the water-closets and sinks, but also the rain-water from a considerable area. When full their liquid contents must soak through the highly polluted gravel soil into the river just above the intakes of the water companies. During the recent heavy rains some of these cesspools have overflowed the surface of the gardens and paved courts, giving rise to an indescribable effluvium. When the river is in flood the condition of the water is too awful to contemplate. In addition to these pollutions certain poor nomads wash their foul linen on Sunday mornings by the river bank in this diluted sewage, so that even apart from overflow fouling pity must be extended to the Londoner who has to drink the water taken from such a source.

ŒSOPHAGOTOMY IN THE INFANT.

THE operation of œsophagotomy is happily so seldom called for that any case in which it has been performed may still prove instructive. One such described by Dr. Lemaistre of Limoges in the *Journal de Clinique et de Thérapeutique Infantile*, June 10th and June 17th, 1897, is peculiar, inasmuch as the patient was the youngest whose age has been recorded—an infant of six months. The foreign body was a leaden brooch 3 centimetres long by 1½ broad, which had been swallowed and had lodged in the gullet just below the cricoid cartilage, where it could be felt with the finger passed down the throat. After it had caused more or less irritation for fourteen days the child was put under chloroform, and the œsophagus, which was found at a depth of 4 centimetres, was opened at its left side opposite the seat of obstruction, the brooch extracted, the wound united with deep sutures—a gauze drain being left

Digitized by Google

in its lower extremity,—and a dry antiseptic dressing applied. After a fortnight the wound had healed. Dr. Lemaistre notes in connexion with this case the tolerance of foreign bodies shown by the œsophagus as compared with the pharynx, and also its great distensibility during life. He gives as the results of dissection of the dead subject approximate measurements of the œsophagus. According to these the total length of this structure at birth is 12 centimetres, that from the cricoid to the interclavicular notch of the sternum 3½ centimetres. At six months of age 1 centimetre has been added to each of these measurements. He advocates a long primary incision from the cricoid to the sternum for this operation, and following the example of H. Schramm,[1] he prefers not to include the mucous membrane in stitching the wound, but would allow its divided surface to unite naturally, thus ensuring a more rapid closure.

CONTAGIOUS DISEASES IN A POOR-LAW SCHOOL.

IN the current number of the *Practitioner* is a very interesting paper by Dr. S. G. Litteljohn upon the above subject. The school in question is the Central London District, and the space of time covered by the paper extends from Jan. 1st, 1871, to the present time. The ages of the children vary from three to sixteen years, and about 14,000 children passed through Dr. Litteljohn's hands in the period. Amongst these 3274 cases of disease occurred; but this does not mean that that number of children were affected, for one child, of course, often had the same disease twice, or had two or more different fevers. As regards seasonal influence, small-pox and diphtheria were diseases of March, April, and May. Chicken-pox was pretty uniformly distributed throughout the year; scarlet fever was most prevalent in December, January, and February, and measles in February, March, June, August, and November. Whooping-cough was most frequent in December, March, February, and April, while influenza was far more common in January than in any other month. Of the deaths 162 in all were due to small-pox, 1 to influenza, 6 to diphtheria, and 20 to scarlet fever. The one fatal case of small-pox, a boy aged ten years, bore no trace of a vaccine scar. Dr. Litteljohn, naturally enough, interpreted the clause of the Poor-law that it is the duty of the medical officer to "vaccinate all children requiring vaccination" as including re-vaccination, and acted on this idea for some years, when he discovered his action was illegal; so the school is now less protected than formerly, but there has been no case of small-pox for thirteen years. We have not space enough to deal with the whole of this valuable paper, but we recommend every medical man to read it.

THE STATE OF THE STREETS.

WE are glad to see that of late there have been various growls in the daily press as to the various dangers and objectionable features to be met with in the streets. They are many and various and we can only notice a few of them. The first and most important from a medical point of view is the abominable custom which is allowed to go on quite unchecked of collecting what is euphemistically known as "waste"—i.e., every kind of kitchen refuse which gives out a filthy odour—at a late hour in the morning. A flagrant instance of this came under our notice the other morning in St. James's-square at 10 A.M. Traffic of this kind should be strictly forbidden except between 1 and 7 A.M. At present—and this brings us to another cause of complaint—the traveller in a crowded street like Piccadilly may easily get blocked on an omnibus just behind one of these pest carts and be nearly poisoned. Progress is constantly being checked by the omnibuses in front and so the nuisance is more or less constant. The number of omnibuses will have to be limited, and in any case they should not be allowed to stop anywhere and as many times as those in charge of them like. A third point, which is rather a matter for the vestries, is to see that there is some reason exercised in watering the streets. We constantly see the steep end of Bedford-street sprinkled with water, rendering it so slippery that for a horse to get up with a heavy load is a terrible struggle, and has often to be given up. The Strand in the meantime, which is just as dusty, is seldom watered. No steep street should ever be watered artificially except for the purpose of being washed. The evils of traffic are increasing, and those we have mentioned are inimical to the health and temper of the community. As to street noises, we suppose something will be done some day, but at present the plague of organs and newspaper "runners" is unabated.

[1] Wiener Medicinische Wochenschrift, 1895.

ARREST OF HÆMORRHAGE IN HÆMOPHILIA BY THE APPLICATION OF HEALTHY BLOOD.

DR. BIENWALD has employed this very original method in the case of a child, aged two years, the subject of hæmophilia.[1] Having failed to arrest the hæmorrhage from a small wound on the face by the application of perchloride of iron, he obtained some blood by aspiration from a healthy subject and deposited it on the wound. In a few minutes it coagulated, and the hæmorrhage at once ceased. His explanation of the action of the remedy is that it supplies the ferment necessary for thrombosis in the small vessels. Whether this is correct or not is impossible to say in the absence of definite knowledge of the pathology of hæmophilia. As affording his explanation some support we may mention the success obtained by Dr. A. E. Wright in his experiments with a solution of fibrin ferment and chloride of calcium as a styptic. Dr. Bienwald's ingenious method certainly deserves a trial.

IN a telegram to Lord George Hamilton the Governor of Bombay has stated that the deaths from plague in Bombay city during the week ending June 25th were 22 out of a total from all causes of 520. In Poona during the same period the total deaths from all causes were 108. One death from plague was reported. The high rate of mortality was due to cholera. In most districts there were either not any, or very few, deaths from plague, with the exception of Cutch, where there were 83 cases and 60 deaths.

MR. W. W. ASTOR has given the munificent annual subscription of £1000 to the Prince of Wales's Hospital Fund, being the largest hitherto received, and another generous person has given an annual subscription of £250. The total receipts up to the present time are, in round numbers, £20,500 in annual subscriptions, £133,150 in donations, and commuted subscriptions to be invested £20,550.

THE treasurer of Guy's Hospital has received a Jubilee gift of £3000 towards the re-endowment fund from a lady who desires to remain anonymous. The interest on this sum will be applied towards the maintenance of beds in Queen Victoria Ward recently re-opened by the Prince of Wales.

AT a meeting of the Council of the Royal College of Veterinary Surgeons, held on the 2nd inst., for the appointment of officers, Professor Pemberthy was unanimously

[1] La Semaine Médicale, May 5th, 1897.

Digitized by Google

elected President, and Sir F. Fitzwygram, Messrs. Simpson, Trigger, Wragg, Mason, and McFadyean Vice-Presidents.

AT a special meeting of the Council of University College, Bristol, held on the 29th ult., Mr. Charles Alexander Morton, F.R.C.S. Eng., L.R.C.P. Lond., and Mr. James Swain, M.D. M.S. Lond., F.R.C.S. Eng., were appointed Joint Professors of Surgery in the Faculty of Medicine.

WE are glad to note that Dr. John Thomas Arlidge has been granted a Civil List Pension of £150 per annum "in consideration of his valuable labours in the cause of public health, and especially his investigation into the hygienic results of particular industries and occupations."

H.R.H. THE DUKE OF CAMBRIDGE has accepted the invitation of the Mayor and Corporation of Harrogate to open the new Royal Baths. July 13th is the day provisionally fixed for the ceremony.

SOME NOTES ON THE LATE GRECO-TURKISH WAR.

ONE of the most lamentable things about the recent war between Greece and Turkey was the inadequacy of provision which the Greek nation made for their wounded, and had it not been for the kindheartedness of foreigners Greece must have borne the stigma of treating her wounded in a way which would have almost discredited a nation far lower in the scale of civilisation. It is on record that a man with a broken femur was strapped straddlewise across the back of a mule and thus carried for several miles, and this is by no means an isolated instance of the barbarity of the methods adopted. For men to be conveyed from a cart to an open boat, again to a wagon, and again to a large steamer was a common occurrence on the Arta side, and many injuries proved fatal or were made much worse by the absence of any efficient means of transport. One man with a bullet wound through the thigh who was brought to the English hospital nearly died in consequence of this means of transport. The wound of exit at the back had been so rubbed by the constant friction of the splint that a large sore or sloughing wound the size of the palms of both hands was the result.

The military hospitals, in which there were no Greek women nurses, were for the most part dirty and quite ill-adapted to the needs of war; the soldiers were put to bed in their regimentals, just as they had come from the war; and operations were performed without chloroform, not from lack of the anæsthetic, but from some occult reason only known to the Greek surgeons. The hospitals, however, which were under the patronage of the Princess were everywhere more clean and well looked after. The English hospital in the Piræus was made up of only about twenty-seven beds; the other one had one hundred. These were the two hospitals organised by the *Daily Chronicle* fund. As regards the situation, the hospital at Piræus was an ideal one situated at the corner of a promontory overlooking the open sea, surrounded by picturesque scenery and pure air.

The cases in the English hospitals were selected on account of their severity and to prevent the further suffering which a removal to the hospitals in Athens would intensify, but they do not call for any special notice. The number of wounded, which in Athens alone amounted to about 3000, was unduly large in proportion to the number killed outright in the battlefield, which, it is stated, was comparatively small. No cases of bayonet wounds were seen in the English hospital, but one-fifth of the cases was produced by shells, or by stones, &c., thrown up by the bursting of shells. The large number of gunshot wounds (Martini) presented an extraordinary similar appearance, the round black holes with white charred edge of entrance and exit being so alike that they might have been painted by the same brush. The chief interest of the wounds lay in the direction taken by the bullets: some passed in the neighbourhood of dangerous or important parts without doing any damage; others passed through joints, and rendered the question of resection a debatable one; whilst those striking bone always produced extreme comminution because of the flat-headed shape of the missiles. These weighed about 1 oz. 1 gr. and resembled 1¼ in. of uncut cedar pencil. Those perforating the abdomen all proved fatal, the bladder, stomach, as well as many parts of the intestine being perforated. It was noticeable that the larger number of men were wounded in the lower extremities, probably the result of long-distance firing or nearly spent shots.

A glance through the following list of 110 cases from the military hospital at Corfu, where the cases were not selected, shows that nearly 50 per cent. were injuries to the hands, the actual figures showing injuries to the left hand 22, and to the right hand 23, total 45. To comment on the peculiar nature of these injuries would perhaps be uncharitable, but the fact is nevertheless significant.

1. Bullet wound in upper arm. 2. Injury to right thumb. 3. Bullet wound through right shoulder. 4. Left first finger. 5. Left first finger. 6. Bullet wound through right thigh. 7. Bullet wound through right shoulder. 8. Amputation of first finger right hand. 9. Amputation of top of first finger left hand. 10. Bullet wound through left hand. 11. Bullet wound through left hand. 12. Bullet wound of left thumb. 13. Amputation of second finger left hand. 14. Bullet wound through right shoulder. 15. Shell wound of right hand. 16 Grazed wound of left side. 17. Amputation of middle finger left hand. 18. Amputation of top of little finger left hand. 19. Amputation of top of first finger right hand. 20. Bullet wound through right wrist. 21. Amputation of top of first finger right hand. 22. Amputation of whole of first finger right hand. 23. Amputation of half of middle finger right hand. 24. Injury and amputation of top middle finger right hand. 25 Gunshot wound and fracture left forearm. 26. Shell wound and amputation of middle finger left hand. 27. Bullet wound through left hand. 28. Amputation of half first finger right hand. 29. Bullet wound and fracture of right hand. 30. Bullet wound through right shoulder. 31. Shell wound instep right leg. 32. Amputation of half first finger right hand. 33. Amputation of first finger left hand. 34. Amputation of half of first finger right hand. 35. Grazed wound of middle finger right hand. 36. Bullet wound transversely across neck and back. 37. Amputation of half of first finger right hand. 38 Amputation of top of thumb left hand. 39. Bullet wound through lower leg right side. 40. Grazed wound of left thumb. 41. Bullet wound through chest (no spitting of blood). 42. Bullet wound right arm to elbow. 43. Bullet through palm of left hand. 44. Grazed wound of right side of head. 45. Amputation of top of finger left hand. 46. Amputation of top of little finger right hand. 47. Amputation of half of index finger left hand. 48. Wound of top of left thumb. 49. Amputation of half of index finger left hand. 50. Amputation of top index finger right hand. 51. Bullet wound through left shoulder. 52. Bullet wound through right upper arm. 53. Bullet wound through left hand. 54. Grazed wound of right side of chest. 55. Bullet wound through left palm of hand. 56. Bullet wound through left foot; amputation of toe. 57. Grazed shell wound of right foot. 58. Grazed bullet wound of left forearm. 59. Amputation of top of little finger right side. 60. Bullet wound between fingers left hand. 61. Contused wound of shell of face right side. 62. Contused wound of shell on left foot. 63. Amputation of first finger left hand. 64. Bullet wound through left upper arm. 65. Grazed wound between thumb and first finger left hand. 66. Amputation of finger right hand. 67. Grazed wound first finger right hand. 68. Amputation of top of first finger of right hand. 69. Bullet through the right foot. 70. Bullet wound through left thigh. 71. Bullet wound across and through shoulders and back. 72. Amputation top of first finger right hand. 73. Amputation top of first finger right hand. 74. Bullet wound through right hand. 75. Bullet wound through right forearm. 76. Bullet wound through left ham. 77. Grazed wound third finger right hand. 78 Compound comminuted fracture of left patella. 79. Bullet wound through back of neck. 80. Amputation top of little finger left hand. 81. Bullet wound through left upper thigh. 82. Bullet wound through left shoulder blade. 83. Bullet wound through left upper arm. 84. Bullet wound graze right chest (no spitting of blood). 85. Bullet wound through left forearm. 86 Bullet wound through upper left forearm. 87. Bullet wound of face (a very interesting case). 88. Bullet wound of left toes. 89. Grazed bullet

Digitized by Google

wound of back of head. 90. Grazed wound between fingers left hand. 91. Bullet wound through left shoulder. 92. Bullet wound across back. 93 Amputation of top of first finger right hand. 94. Bullet in left thigh; no fracture; removed. 95. Penetrating bullet wound left foot. 96. Penetrating bullet wound across right side of face and eye. 97. Bullet wound of left buttock. 98. Bullet wound of right calf. 99. Bullet wound across abdomen; flesh wound. 100. Grazed wound across top of head. 101. Bullet wound across right knee joint (officer). 102 Meningitis, after bullet wound across back of head. 103. Knocked down, and bruising of left side. 104. Incised wound of left foot. 105. Contused wounds of both calves. 106. Swollen and burst feet. 107. Fell from mountain, graze of head, and spat blood. 108 Amputation top of first and second finger right hand. 109. Penetrating bullet wound left upper thigh. 110. Bullet wound through left foot.

It is only right to state that the success of the arrangement of the larger English hospital was due to the experienced aid of Mr. S. Osborn, F.R.C.S., chief surgeon to the St. John Ambulance Association.

STATISTICS OF CHOLERA.

OUR Special Correspondent in Egypt sends us the following figures showing how cholera was distributed throughout the various districts of Egypt during the epidemic which lasted from October, 1895, to November, 1896:—

Town or province.	Number of villages attacked.	First case.	Last case.	Total cases.	Total deaths.
Cairo	—	Dec. 7th	Oct. 21st	1519	1349
Alexandria	—	Dec. 28th	Nov. 3rd	1072	914
Port Said	—	July 14th	Sept. 24th	23	20
Suez	—	May 3rd	Oct. 11th	23	15
Ismailia	—	June 12th	Aug. 31st	14	14
Damietta	13	Oct. 11th	Sept. 16th	528	467
Gharbieh	143	Dec. 1st	Oct. 20th	4425	3503
Dakahlieh	52	Oct. 13th	Sept. 29th	1359	1127
Charkieh	96	Oct. 26th	Sept. 25th	1446	1137

THE METROPOLITAN WATER SUPPLY.

The Royal Commission.

A MEETING of the Royal Commission was held at Trafalgar-buildings, Charing-cross, on Tuesday last, Lord Llandaff presiding. Matters relating to procedure were discussed, and the commissioners have had under consideration the question of the appearance of counsel before them, a proceeding to which they are willing to consent within limitations.

The County Council and the Royal Commission.

The Water Committee of the London County Council have had before them a communication from the Royal Commission stating that the commissioners will be prepared to receive evidence from the Council upon the points referred to them for consideration. The Water Committee are now considering the evidence which is to be presented by witnesses on behalf of the Council, and have prepared a series of resolutions which, they believe, will represent the opinion of the large majority of the Council, and which they hope that the Council will pass at the next meeting.

These resolutions are to the effect that (1) the water-supply of the metropolis should not continue in the hands of private companies; (2) that the undertakings of the metropolitan water companies should forthwith be purchased at a fair and reasonable valuation; (3) that the management of the water-supply should be effected either (*a*) by the London County Council supplying its own area directly and outside authorities in bulk at a fixed price; or (*b*) by the London County Council supplying its own area only, and the outside authorities supplying their areas; or (*c*) by a new body supplying directly the whole area both within and without the county; and (*d*) that, in any case, it is desirable that the London County Council should, in the first instance, be the purchasing authority on behalf of the population of the whole area concerned.

A further resolution suggests that if the undertakings of the water companies are not acquired, it is essential that effective powers of control should be given to the London County Council, and that the legal position of the companies should be re-considered.

"The Water Famine in South London."

The area affected by the recent break-down in the water-supply in the Lambeth Company's district was certainly a large one. The break-down, it will be remembered, was said to be due to a difficulty with the filter beds at Ditton. The engineer of the company wrote to one of the customers who complained of the failure of the company to supply him with water, and in his letter he mentioned that the area affected by the break-down was a large one, and gave that as one of the reasons why every customer could not be informed that the water-supply would for a time be deficient. As far as we have seen, Mr. Andros, the writer of the original letter of complaint, is the only customer in the Lambeth district who has made a public complaint on the matter, but many letters on the subject were received by the Penge Vestry. The Lewisham Board of Works in a debate upon the subject did not mince matters; but the board had before them evidence to show that the sudden stoppage of water had placed certain workmen in grave peril. On the motion of the chairman of the board it was agreed that a very strong letter should be written to the company especially complaining that the company did not give notice of the failure of the supply. The dearth of water lasted three or four days, and it would have been easy for the company to have given notice to the public on the first day. Then the public could have economised what water they had and have taken precautions against accident.

East London Waterworks.

We understand that the East London Waterworks Company are now supplying water from their new reservoirs, the East and West Warwick. We lately gave a full description and plan of these reservoirs in THE LANCET. The water from them passes through a meter house which has been recently erected, and is fitted up with a Venturi meter capable of registering an amount up to 60,000,000 gallons a day.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF FELLOWS.

THE half-yearly meeting of Fellows of the College was held on July 1st, immediately after the election to the Council, the result of which was published in our issue of last week, *vide* p. 67; the President, Sir WILLIAM MAC CORMAC, Bart., was in the chair.

Forty-eight Fellows, including fourteen members of the Council, were present.

The PRESIDENT reported that the Council had received a letter from Lord Lister in which he requested that his

Digitized by Google

warmest thanks might be expressed to the Fellows for their kind congratulations.

Mr. R. B. ANDERSON moved:—

"That, as asked in a memorial dated May, 1897, of Fellows and Members practising in Plymouth, Devonport, and Stonehouse and the neighbourhood, and in reference to resolutions of previous meetings of Fellows and Members, the Council be requested to afford the College some explanation as to the rights referred to in Section XV. of the College By-laws; and particularly why Fellows and Members are in error in regarding the violation of the right to practise their profession as a disturbance in the exercise of a right acquired by them as Members of the College, and the Council's undertaking to protect and defend Fellows and Members so disturbed as a binding obligation."

He said that the Council had been requested by the memorialists to subscribe to the fund for obtaining a rescinding of the judgments which had been given against him, but that they had said that Section XV., which promised to maintain the rights of Fellows and Members when interfered with, did not apply to his case. The Council was then requested to explain what were the rights referred to in the by-law, but they had replied "they did not think it incumbent upon them to give explanations of the conclusions at which they might arrive, but were of opinion that Mr. Anderson's case did not come within the terms of Section XV. of the by-laws." The resolution he was bringing forward was to ask the Council to give some explanation of the rights and privileges which were mentioned in the by-law. It was most important that the Fellows and Members should know what were the rights which the Council would maintain. So far as he could see, the only right to which the by-law could refer was the right to practise surgery; this was acquired by becoming a Fellow or Member of the College. The silence on the part of the Council was very significant, and he urged the meeting to carry this resolution, which formally requested the Council to give the explanation of what rights were referred to in Section XV.

Mr. GEORGE JACKSON seconded the resolution.

The PRESIDENT said that Mr. Anderson's case had been before the Council many times. They all felt the greatest sympathy with him for the way in which he had been treated, but they had come to the conclusion that the College funds could not be employed for such a purpose, and that help for Mr. Anderson must come out of their own pockets. The College was for the promotion of surgery, and the good work it had done in its museum, its library, and its laboratories was acknowledged by all; it would be an entirely new departure to contribute to the maintaining of actions at law, however deserving the Fellow or Member affected might be. He would like to ask Mr. Anderson if it were true that there was no part of the British Empire where he could not practise?

Mr. F. J. GANT said that he had always taken a very warm interest in Mr. Anderson's case, but the College had no right to contribute from its funds to such a purpose; he would move an amendment:—

"That having heard the President's explanation in reference to the action of the Council in Mr. Anderson's case, this meeting, while expressing sympathy with Mr. Anderson, suggests [to the Council] that no further action be taken in this case."

Sir ROBERT CRAVEN seconded the amendment.

Mr. ANDERSON thanked the meeting for the offered sympathy, but urged that sympathy afforded no relief from his persecutions. The explanation of the President did not really touch the question of the meaning of the by-law. As to the question which he had been asked, it was not a fact that he could practise in Tobago in the same way as other Fellows of the College could; the judgments against him were still in force, and until these were rescinded it was practically impossible for him to practise there. About £900 would be required to carry his appeal to the Privy Council.

On being put the amendment was carried by 25 votes to 4, and on being put as a substantive motion, it was carried by 29 to 1.

Mr. ANDERSON then moved his second resolution, which was as follows:—

"That this meeting desires to call the attention of the Council to the published reports of the proceedings of the General Medical Council at the recent session in the matter of a petition of a Fellow and Member praying for the defence by the General Medical Council of his rights guaranteed under the Medical Acts, and to Mr. Bryant's action in the matter; and to inquire whether, in voting against the reception of the petition and its entry on the minutes, and in accepting the advice of the Council's legal adviser without considering it in relation to the merits and prayer of the petition, Mr. Bryant (*a*) correctly construed the views of the Council on the subject, or (*b*) acted satisfactorily as the representative of the Council on the General Medical Council."

Mr. GEORGE JACKSON seconded.

The PRESIDENT said that Mr. Bryant had been asked to represent the College on the General Medical Council; that no course of action had ever been dictated to him, but he was expected to act according to his own judgment, and that no other arrangement would be satisfactory to the College or to Mr. Bryant.

Sir ROBERT CRAVEN suggested that Mr. Anderson should appeal to the profession for the money necessary to carry on his actions.

The resolution was put and lost.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Enteric Fever in the City of Chichester, by Dr. T. BULSTRODE.[1]—This occurrence took place in the months of May to September of last year, and it has interest because it seems most clearly to have been brought about in the main by conditions of pollution of soil apart from the question of the influence of such pollution upon the water-supply. Chichester has long had a bad repute as regards the prevalence of enteric fever. It was inspected by the late Dr. Seaton in 1865 and again by Dr. Airy in 1879, and for some twenty years its "fever" death-rate has been largely in excess of that of the county in which it is situated, and also in excess of that for England and Wales. Among the points which are worked out with much care by Dr. Bulstrode is the fact that the locality invaded—namely, one situated outside the old walls—is the same as that which had been invaded before. Then it is shown that the incidence of the disease could not have been due to imperfections in a new system of sewerage—indeed, only one house inside the walls that was drained became infected; and, lastly, it appears that the public and private water services could not have induced the disease. Thus, of 494 houses inside the walls which receive the public service of water only 3 were invaded; and taking all the well waters it appears that of 76 houses invaded within and outside the city walls the rate of attack on well-water drinkers was 2·9 per cent., and that on town water drinkers was 2·6; in other words, it was practically equal. But the fouling of soil about houses, and this notably in the locality infected, is about as bad as it could be. Everywhere cesspools and cesspits, disused or still in use, abound. Chichester is "riddled with them," and when houses are sewered or have proper closets provided all the reeking filth of the past is merely covered in and left there to foul and infect the soil. The case is one in which the perpetuation of enteric fever seems to have been ensured by reason of maintaining the foul condition of the soil, and in this sense the report, which is well illustrated, has distinct interest for students of epidemiology.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Southampton Port District.—During 1896 the Admiralty selected Southampton as the port of the embarkation and disembarkation of troops, and although, as Mr. Wellesley Harris observes, this step may be held to be good for the port in a commercial aspect, it undoubtedly increases the risks to Southampton of the importation of exotic diseases, a risk which has been very materially increased during the recent trooping season, owing to the presence of bubonic plague at Bombay, whence came a large number of troops. Each troopship carries on an average, Mr. Harris tells us, some 1250 troops, together with a crew of about 170 Lascars. Arrangements have, it appears, been made by which an officer of the Army Medical Department assists Mr. Harris in his duties in connexion with troopships, and the courtesy of the military authorities, as also of the Customs, is a matter of grateful acknowledgement on the part of Mr. Harris. We expect, too, that no inconsiderable share of the success of the arrangement is due to the valuable assistance which Mr. Harris is able to afford and to the tactful manner in which he carries out his arduous duties. The trade of the port of

[1] Eyre and Spottiswoode, East Harding-street, E.C.; John Menzies and Co., Edinburgh and Glasgow; Hodges, Figgis, and Co., Dublin. 1897. Price 6d.

Digitized by Google

Southampton is rapidly increasing, and the net tonnage of the vessels entering the port during last year amounted to 3,596,945, as against 2,562,549 in 1892; and it is a fortunate matter, having regard to the increased risk which this amount of shipping entails, that the Southampton Port Sanitary Authority have adopted a liberal, far-seeing policy in their arrangements. An interesting instance of the danger of eating raw mussels procured from near the main sewer outfall is recorded by Mr. Harris. Three sailors who had thus eaten were attacked with vomiting and diarrhœa, and two of them subsequently developed what appears to have been enteric fever. A somewhat unique point in connexion with the attacks of gastritis is that the symptoms did not develop until some six days after the consumption of the mussels, while in the majority of cases of a similar nature the onset of the symptoms has been within a few hours of the ingestion of the mussels. Under any circumstances it would be well, it seems to us, if a notice were erected near to the sewer outfall warning persons as to the danger of consuming mussels found in its vicinity.

Worcester Urban District.—The chief feature in the sanitary history of Worcester during 1896 was an epidemic of diphtheria which caused 49 deaths among 317 notified cases. The outbreak is the more interesting inasmuch as there is no record of a previous epidemic in the city, the deaths in any one year from 1873 to 1889 having never exceeded 8 in number, while the total for the whole seventeen years was but 43. Since 1892 the deaths have been somewhat more numerous, but no outbreak has occurred. From the monthly notification returns it seems that diphtheria commenced to be epidemic in May, but it has to be noted that in the first quarter of the year sore-throat was prevalent in the district, and that there occurred in addition 16 cases, with 5 deaths, from diphtheria. Of these 16 cases, 3 only were of school age. In April 3 cases occurred, and 2 of these were children attending an infant school; while in May, out of the 11 cases notified, 8 were of children attending school, and other 2 in families members of which went to school, the remaining case having presumably no relation to school attendance. Throughout the epidemic there were 155 scholars, from 21 schools, who suffered from diphtheria, figures which do not include secondary cases which occurred in the houses primarily invaded by school attending cases. There were but five schools which were invaded by the disease in a marked degree, none of the other schools having contributed more than 10 cases each; and amongst the scholars attending school in the poorest and most unhealthy part of the town there was but one notified case. In all there were 254 houses invaded, and in 58 the first notified case was of a person not attending school. Dr. Mabyn Read thinks that "the aggregation of children in schools is the main factor in the spread of this and other diseases." It is, of course, necessary to be careful in the use of the term "main factor," inasmuch as it is obvious that in certain outbreaks of diphtheria it is by no means easy to demonstrate, or even legitimately to infer, that "school influence" is the "main factor"; and it is perhaps more precise to say that under certain conditions, and when the disease is exhibiting a high degree of infectivity, the aggregation of children at susceptible ages in schools may be, and often is, a very potent, or even the main, factor in disseminating the disease. If this be a correct thesis it is to be expected that, as these opportunities for the favourable operations of infectivity increase, even so will what may be termed the natural variations of the diphtheria in any given locality tend to be influenced. By natural variations we mean here those remarkable ascents and descents of diphtheria prevalence for which we have as yet found no adequate explanation, and it is further necessary to insist that these variations often manifest opposite tendencies in different localities. The history of Birmingham may be taken as a good example. Here prevalence of the disease has been falling since 1873, but in the autumn of 1894 a rise commenced which has reached in 1896 a point hitherto altogether unknown in the district. Dr. Read remarks that his "experience goes to show that it is not the pronounced cases of diphtheria that spread the disease, but those ill-defined sore-throats seldom seen by medical men." This is surely the key, in a sense, to much that has been affirmed and denied in reference to school influence, and all of us who have had experience in outbreaks of diphtheria can recall numerous instances where the first *notified* case was not attending school, but where he or she had been infected by a school-attending brother or sister who was found to have been the subject of mild but unrecognised diphtheria. In a word, notification tells us only of that which is recognised, and not necessarily of that which may have been the origin of the outbreak, and which may still be causing its spread. School closure in the Worcester outbreak appears to have been attended with good results, but it would have been of interest had Dr. Read furnished the daily and even weekly notification returns in connexion with each school area, together with the dates of closure and of re-opening of each school.

Coventry Urban District.—THE LANCET of April 17th, 1897, contained an obituary notice of Dr. Mark Anthony Fenton, the medical officer of health of Coventry, and since that date his annual report for 1896 has reached us. Dr. Fenton was compelled to relinquish his life's work on March 27th, but he had prior to this completed his annual report, and the town clerk has been able to edit it. The year 1896 was for Coventry one of unexampled prosperity for the cycle and allied industries; large numbers of mechanics were attracted from other districts, while the employés from the Coventry watch and ribbon trades came over to the cycle industry, movements which, Dr. Fenton observed, changed the character of the working population and led to a marked diminution in outdoor relief and in the number of inmates in the workhouse. During the year under review the compulsory notification of measles, which has been in force in Coventry for the last five years, was abolished, and it has to be noted that from 1877 until the adoption of compulsory notification a system of voluntary notification was in force for this disease. The following table will be of interest:—

Period of Voluntary Notification.

—	Cases notified.	Deaths.	Death-rate per 1000 population living.
Five years ending 1881	774	43	1·0
" " 1886	2872	87	2·0
" " 1891	2556	82	1·6

Period of Compulsory Notification.

—	Cases notified.	Deaths.	Death-rate per 1000 population living.
Five years ending 1896	4020	95	1·7

There were epidemics in 1882, 1884, 1886, 1889, 1891, 1894, and 1896. The measures adopted were the distribution of printed instructions and the prohibition from school attendance of children from invaded houses. The conclusion to be drawn from the experience at Coventry is, Dr. Fenton added, that notification without isolation is not of much practical value, and he thought that the provision of hospital accommodation for a small number of cases so as to isolate the initial centres of infection might do good. The Gloucester outbreak of small-pox proved a temporary benefit to Coventry in the matter of vaccination, and the guardians, who previously had refused to prosecute, rescinded the resolution embodying that determination. The result was that the percentage of children vaccinated rose from 4·5 in 1895 to 41 in 1896. Dr. Fenton was of opinion that if the pseudo-voluntary system suggested by the Vaccination Commissioners becomes law vaccination in Coventry will soon disappear.

Norwich Urban District.—Dr. H. Cooper-Pattin welcomes the formation in Norwich of a "Sanitary Aid Association," which he thinks will do useful work in the direction of stimulating public opinion, and thus in aiding the efforts of the sanitary authority. Clergy of all creeds have joined the association, and its constitution is such as to command respect. The isolation hospital at Norwich seems to be popular, but unfortunately the accommodation is inadequate for the needs of the city, and instead of there being one bed to every 1000 of the population there is but one to every 2250. As a result of this deficiency first cases of scarlet fever occurring in a house were often during last year unable to be removed, and hence other children contracted the disease.

Digitized by Google

Dr. Cooper-Pattin thinks that damp, foggy weather, particularly when it is associated with low barometric pressure, tends to produce a congested state of the tissues lining the fauces and thus predisposes to attacks of diphtheria. There were 196 cases of enteric fever notified in Norwich last year, and Dr. Cooper-Pattin has gone very thoroughly into the distribution of the cases in regard to the several factors which may have been concerned in their causation. The chief conclusions at which he arrives are these: that enteric fever has been prevalent in Norwich for the last sixteen years, and that the endemicity of the disease is connected n some degree at least with the methods of excrement disposal which obtain in the city; that emanations from sewer gratings, untrapped gullies, &c., exert a predisposing influence on those exposed to them; and that the thousands of fixed and movable "bins" pollute the soil and air in the vicinity of dwellings, and thus afford a favourable nidus for the disease germs. As evidence of soil pollution Dr. Cooper-Pattin calls attention to the high proportion of chlorides and nitrates to be detected in the soil of the city.

Maidstone Urban District.—During last year the water in one of the reservoirs supplying the town became polluted in rather an unusual and interesting fashion. Attention was first called to the fact that the water in question was polluted through the regular analyses which are made of the public water-supply, and an illustration is thus afforded of the value of these analyses. It seems there are two reservoirs, one known as the new and the other as the old reservoir, situated one on either side of the road and of the sewer which passes along it. The new reservoir is at a higher level than the sewer, the old reservoir at a lower level. The springs furnishing water to the reservoirs rise to the west of the new reservoir, and the water thus traverses the road containing the sewer before reaching the old or low-level reservoir. In explaining how the pollution took place Mr. M. A. Adams points out that when the level of the spring water is, as it usually is, at a higher level than the sewer the water tends to pass through any leak in the sewer pipes into the sewer; but, on the other hand, when, as was recently the case, the water is at a lower level than the sewer the reverse process takes place, and the sewage tends under certain circumstances to pass out into the surrounding soil, and subsequently to be carried with the spring water into the lower reservoir. All this, Mr. Adams adds, exactly fits in with the facts and circumstances of the case, and the water from the lower reservoir has not since been used.

Plympton St. Mary Rural District—Mr. Noy Scott complains of the nuisance caused in his district by the refuse from Plymouth know as "Plymouth dung." This refuse is stated to be stored by the contractor until it becomes offensive, when it is sold to farmers, who spread it on the land for manure. Mr. Noy Scott reports that the refuse causes sickness in people who are brought in contact with it, and he urges that something should be done to abate the nuisance. It seems that the most effectual and probable remedy is the provision of a destructor by the Plymouth Corporation. Proposals for the erection of a joint isolation hospital in connexion with this district have fallen through, but the district council have obtained permission to lease a piece of ground on which a small pox hospital can at any time be erected, and the medical officer of health has been empowered to purchase a temporary hospital if necessary. We trust the building will be in place in time for the isolation of the first case, but it would be surely better if the council followed the advice of their medical officer of health and procured the site and hospital before this case arises.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 7115 births and 3106 deaths were registered during the week ending July 3rd. The annual rate of mortality in these towns, which had been 15·8 and 15·7 per 1000 in the two preceding weeks, further declined last week to 14·7. In London the rate was 13·5 per 1000, while it averaged 15 6 in the thirty-two provincial towns. The lowest death-rates in these towns were 10·3 in Croydon, 11·4 in Halifax, 11·5 in Leeds, and 11·6 in Derby; the highest rates were 20·1 in Liverpool and in Burnley, 21 0 in Salford, 21·9 in Plymouth, and 25·4 in Preston. The 3106 deaths in these towns included 409 which were referred to the principal zymotic diseases, against 355 and 404 in the two preceding weeks; of these, 156 resulted from measles, 82 from diarrhœa, 77 from whooping-cough, 41 from diphtheria, 34 from scarlet fever, and 19 from "fever" (principally enteric). No deaths from any of these diseases were recorded last week in Swansea, in Derby, or in Halifax, while they caused the highest death-rates in Manchester, Salford, Burnley, Preston, and Plymouth. The greatest mortality from measles occurred in Bolton, Newcastle-upon-Tyne, Birmingham, Manchester, Salford, Burnley, and Preston; from scarlet fever in Leicester; from whooping-cough in Norwich, Oldham, and Plymouth; and from diarrhœa in Burnley and Plymouth. The mortality from "fever" showed no marked excess in any of the large towns. The 41 deaths from diphtheria included 32 in London and 2 in Liverpool. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2821, against numbers increasing from 2380 to 2789 on the nine preceding Saturdays; 310 new cases were admitted during the week, against 255, 274, and 267 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 140 and 142 in the two preceding weeks, declined again to 127 last week, and were 70 below the corrected average. The causes of 35, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Wolverhampton, Birmingham, Norwich, and Leicester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·4 per 1000 in each of the two preceding weeks, declined to 18·7 during the week ending July 3rd, but exceeded by 4·0 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·3 in Aberdeen and 17 0 in Perth to 21·7 in Paisley and 33·2 in Leith. The 557 deaths in these towns included 23 which were referred to diarrhœa, 21 to whooping-cough, 16 to measles, 10 to "fever," 5 to scarlet fever, and 2 to diphtheria. In all, 77 deaths resulted from these principal zymotic diseases, against 87 and 69 in the two preceding weeks. These 77 deaths were equal to an annual rate of 2·6 per 1000, which was 0·7 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had declined from 40 to 16 in the four preceding weeks, rose again to 21 last week, of which 10 occurred in Glasgow, 6 in Leith, and 3 in Edinburgh. The 16 deaths from measles showed a further decline from the numbers recorded in recent weeks, and included 9 in Leith, 4 in Edinburgh, and 3 in Glasgow. The deaths referred to different forms of "fever," which had been 5 and 6 in the two preceding weeks, further rose to 10 last week, of which 9 occurred in Glasgow. The 5 fatal cases of scarlet fever included 2 in Glasgow and 2 in Edinburgh, and the 2 deaths from diphtheria were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 109 and 104 in the two preceding weeks, declined again last week to 86, but exceeded by 11 the number in the corresponding period of last year. The causes of 47, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·7 and 21·8 per 1000 in the two preceding weeks, declined again to 20·3 during the week ending July 3rd. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 27·3 per 1000, the rate during the same period being 15·5 in London and 24·9 in Edinburgh. The 136 deaths registered in Dublin during the week under notice showed a decline of 10 from the number in the preceding week, and included 11 which were referred to

Digitized by Google

the principal zymotic diseases, against 14 and 11 in the two preceding weeks; of these, 4 resulted from diphtheria, 2 from measles, 2 from scarlet fever, 2 from diarrhœa, and 1 from whooping-cough. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·5 in London and 2·0 in Edinburgh. The fatal cases of diphtheria, which had increased from 1 to 5 in the three preceding weeks, declined to 4 last week. The mortality from measles, whooping-cough, and diarrhœa corresponded with that recorded in the preceding week, while that from scarlet fever showed an increase. The 136 deaths in Dublin last week included 22 of infants under one year of age, and 25 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the numbers returned in the preceding week. Five inquest cases and 5 deaths from violence were registered; and 55 or more than a third, of the deaths occurred in public institutions. The causes of 11, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR HERBERT J. R. MOBERLEY will shortly join at Woolwich. Surgeon-Captain Alfred P. Blenkinsop proceeds to Dublin for duty.

ROYAL HORSE GUARDS.—Surgeon-Lieutenant-Colonel H. F. L. Melladew, M.D., is placed on retired pay. Surgeon-Captain Henry Mitchell, from 2nd Life Guards, to be Surgeon-Major, in succession to Surgeon-Lieutenant-Colonel Melladew.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel Moore, A.M.S., has been directed to proceed to Poona to officiate as Principal Medical Officer, Poona District, vice Surgeon-Colonel Atkins, A.M.S., proceeded on leave. Brigade-Surgeon-Lieutenant-Colonel Charles John Walford Meadows, Bengal Establishment, retires from the service, subject to Her Majesty's approval.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain James Cagney, M.D., 20th Middlesex Volunteer Rifle Corps, to be Surgeon-Captain.

MILITIA.

Infantry: 3rd Battalion the Connaught Rangers: Honorary Surgeon-Major G. W. Hatchell resigns his commission, also is permitted to retain his rank and to wear the prescribed uniform on his retirement.

VOLUNTEER CORPS.

Artillery: 1st Essex (Eastern Division, Royal Artillery): Charles Forsyth, M.B., to be Surgeon-Lieutenant. *Engineers:* 2nd West Riding of Yorkshire (Leeds): Henry Waite, gent., to be Surgeon-Lieutenant. *Submarine Miners:* The Tees Division: John Watkin Edwards, M.B., to be Surgeon-Lieutenant. *Rifle:* 4th Volunteer Battalion the Durham Light Infantry: The under-mentioned Surgeon-Lieutenants to be Surgeon-Captains: T. Benson and H. A. Collinson, M.B. 1st Dumbartonshire: David Christie, M.B., to be Surgeon-Lieutenant. 18th Middlesex: Surgeon-Major Anthony Hickman Morgan, D.S.O., retired, late Army Medical Staff, to be Major.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies: Surgeon-Lieutenant J. B. McKenzie Anderson, M.B., to be Surgeon-Captain.

THE MOSCOW CONGRESS.

As an inducement to Service members of the profession to attend the Twelfth International Congress at Moscow from August 19th to 26th next, the organising committee of the tenth Section (military medicine and hygiene) offer free lodging in the wards of the Surgical Clinique to a limited number of their foreign colleagues. The institution was evacuated on June 1st in order that the whole of the interior might be repainted, washed, and thoroughly cleansed, and all the beds and bedding are to be scrupulously disinfected. There is room in the building for seventy-five persons, of whom eighteen can have separate apartments, the remainder being accommodated in wards containing from four to eight beds. Lodging in Moscow is no doubt both hard to find and expensive when found, so probably medical officers will be glad to avail themselves of the kind and thoughtful invitation of their Russian *confrères*.

OUTBREAK OF CHOLERA AT MUTTRA.

We learn, on the authority of the *Times of India* of June 18th, that there has been a sharp outbreak of cholera among the men of the 5th Lancers at Muttra, fifteen deaths having occurred out of twenty-three seizures.

It is estimated that there are at present some fifty vacancies in the Army Medical Service to be competed for at the next examination, the same number in the Medical Service of the Navy, and eighteen are notified in the Indian Medical Service.

"THE LUNACY ACT, 1890, AND ITS AMENDMENTS."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "Formerly a County Asylum Superintendent," I am glad to see, suggests as a remedy for the present evils the *abolition of lunacy certificates*. I have long maintained that the lunacy certificate should be abolished as constituting a grievous interference with the liberty of the subject in obtaining medical treatment. That a person suffering from disease of the brain must obtain, or have obtained, the authorisation of a magistrate before going to a sanatorium for treatment would be grotesquely absurd if it did not cause such serious evil. The public would rebel at once if the lawyers demanded that a man with a broken leg should be haled before a magistrate prior to being taken to a hospital. The broken leg can be seen, but unfortunately the broken brain is not so visible.

If there is danger of asylums admitting or retaining sane persons these institutions should be so supervised as to render this impossible, and this supervision should be accomplished by supervisors appointed and paid by the State. If the medical profession possessed any solidarity it would not tolerate for a moment the present position of matters. The duty of signing certificates and of making reports in regard to these sick persons is not only thrust upon medical men by law, but these laws are conceived and directed against the profession very much as if against the habitual criminal class.

The result of all this insane legislation, as it may appropriately be called, is that to avoid certification, or from fear of it, patients are kept from appropriate treatment, with the consequence that homicides and suicides are rife, while cases that might have recovered become chronically insane. A second result is that asylum medical officers have half their time occupied in filling up endless forms, reports, statements, &c., many of them utterly absurd and useless, but one at least, the periodical certification form, positively prejudicial, having often resulted in the discharge of dangerous lunatics. The proportion of medical officers in asylums is wofully small, and with the ever-increasing addition to the always heavy duties of administration little time or energy is left them for the treatment of their patients. The Lunacy Laws, indeed, are probably the most efficient cause in preventing that popular subject, "the increase of insanity," becoming "the decrease of insanity." The disease is clear, but what is its cause and what the remedy? The cause is patent and obvious. The Lord Chancellor is at the head of the lunacy system. Hence the anomaly of a Lunacy Commission, entrusted with the supervision of the treatment of insanity throughout the kingdom, being mainly composed of barristers. This ridiculous state of affairs is about comparable to what should obtain if the Lord Chancellor were supreme over the Admiralty, when no doubt we should see an equal number of barristers and naval officers commanding our fleets, while our captains

Digitized by Google

of ships would spend all their time in forms and correspondence in regard to why Jack had had his grog stopped.

For many years past I have taken part in representations, petitions, and deputations to successive Lord Chancellors in regard to lunacy legislation, and I am fully convinced that this is waste of energy. The remedy for the present wretched state of affairs is to approach Parliament directly, with a view to have the Lord Chancellor's jurisdiction only over the property of the insane, but to place lunatics for their care and treatment under the charge of a Minister of Public Health. I would suggest the formation of an association to promote this object, and should be glad to hear from others interested in, and willing to work to, this end.

I am, Sirs, your obedient servant,

July 5th, 1897. HENRY RAYNER, M.D. Aberd.

THE GENERAL MEDICAL COUNCIL AND THE QUESTION OF MEDICAL REGISTRATION IN INDIA.

To the Editors of THE LANCET.

SIRS,—It will please hundreds of your readers, both at home and in our great Indian Empire, if your excellent proposals for definite action being taken by the General Medical Council are followed out by that august body. There is a simple task before our medical legislators, and, in common fairness to our brethren in the East, they ought to take it up most cheerfully. Could not the registrar of the Council invite the kind attention of the president to the subject, or, failing that, would not some member of the Council befriend India's cause by placing a motion with reference to medical registration in India before the next meeting of that body? Meanwhile I should like to draw further public attention to the able article on this question in THE LANCET of July 3rd by placing before the profession the following article taken from the *Indian Medical Record*, a journal that has worked hard for years to obtain a Medical Registration Act for India:—

"Any Act of the legislature which contemplates the protection and registration of medical practitioners in India has a very complex problem to solve. Side by side with the large body of orthodox doctors, is an innumerable host of indigenous practitioners, whose methods, widely differing as they do from western medicine, still command a very wide sphere of employment and confidence with the purely Indian communities. Kobirajes, hakims, vaids, &c., are acceptedly medical practitioners of certain systems, and any Act contemplating registration of medical practitioners must deal with these classes also. They are part and parcel of the domestic life of the people of the country, and they cannot, and must not, be ignored. That their varied systems possess much that is effectual and commendable in the treatment of disease is freely admitted by Western physicians. But that their practices are often based upon most imperfect and distorted suppositions of the anatomy and physiology of the human organism, are facts still more patent. It is to this deficiency in their systems of a fundamental knowledge of pathology, that most of the fatal errors of these indigenous practitioners are due. A little knowledge is admittedly a dangerous thing. And yet it is a glaring fact that these men are often absolutely illiterate and utterly devoid of the faintest knowledge of the position of the organs they are supposed to be treating, and have only traditional ideas of the virtues and actions of the drugs they prescribe. It is as reasonable and right to expect the man who poses as a healer of disease to possess a knowledge of the organs he is dealing with as it is to compel efficiency in mechanical and engineering science in the man who takes charge of a steam engine. It is as reasonable and right to raise standards of efficiency for medical servants of the public as it is to demand and enforce education, training, and experience in engineers, boiler-makers, ship captains, plumbers, and every other practitioner of every other art. It does not follow, because centuries of public or State neglect and indifference have left medical practitioners to ply their art without let or hindrance in this country, that such neglect and indifference towards the public should continue for ever. We have endeavoured by repeated articles upon the subject of medical practice in India to prove that no excuse exists for the withholding of a Medical Registration Act by the Government. The only objection that has been raised has reference to the question of the incorporation of indigenous practitioners within the scope of any such enactment. We would most cordially commend in the first instance that legislation should embrace all practitioners. That kobirajes, hakims, vaids, &c., be enrolled into separate lists and that registration be most carefully and exhaustively made of each and all of them, with a distinct understanding that after the date of registration no man shall be permitted to practise medicine by any system whatever, except he can produce evidence of a fair standard of general preliminary education and proof of attendance for a certain period at a recognised college of medicine for the study of human anatomy, physiology, the pathology of diseases, and also the practical instruction of a hospital or of some registered practitioner of medicine. Surely this is a reasonable demand. We only ask that the kobiraj, the hakim, or the vaid, who seeks to attend the public, should be able to provide that public with some guarantee of his knowledge of his profession. It would be essentially necessary in the case of all these practitioners to demand a certain number of years of practical study with a member of his craft, and his examination by a duly appointed body of his particular system, to ascertain his fitness to practice his art. After undergoing such education and examination as the State would enact, he would be registered as a kobiraj, hakim, vaid, &c., as the case might be.

"The rapid growth and development of medical education in India, as seen by the thoroughly well-equipped medical schools and hospitals to be found in every province, and, indeed, in almost every large subdivision of such province throughout this country, has rendered the acquirement of a practical, intelligent, and reliable knowledge of anatomy, physiology, pathology, and materia medica—the fundamental studies on which the superstructure of rational medicine is built up—a very easy and cheap accomplishment. Men of the country possessing the necessary preliminary educational requirements may go through the whole curriculum of a medical collegiate training of five years' duration by the expenditure of the modest sum of five rupees monthly in any Government college. Surely this is cheap enough!

"With these easily accessible and inexpensive means of obtaining an education in anatomy and physiology, it would be no hardship to compel every candidate for medical practice, by any and every particular system, to acquire such knowledge.

"If the indigenous systems of medicine are worth anything, this process of compulsory education would certainly put them on their mettle. It would cause research into their hidden virtues, reform of their defects, and ultimately lead to their due and proper recognition in the interests of humanity at large. In time, all that is good and useful in them would find its way into other systems. Hence the adoption of a uniform plan of preliminary education and medical training would, in all probability, cause a coalition of the now diverse and imperfectly understood indigenous systems into a harmonious and regulated standard of medical practice throughout the Indian Empire.

"Our object in advocating the early adoption of State regulation of medical practice is not to deprive the poor of their present methods of medical relief, or to exclude the older systems, and in their place force *nolens volens* upon the people the system we represent. Our cry is reform; our object is the advancement of the public good. Regulation, not lawlessness in practice; growth and development, not stagnation; improvement, not annihilation. This is our policy. And in this we claim the sympathy and good judgment of all practitioners of medicine, be they Western or Eastern. Upon the lines we have here enunciated, a complete and comprehensive system of medical registration may at once be enacted, without clashing with any of the social customs of the people of the country, or in any way conflicting with the varied interests of the present complex community of medical practitioners in India."

This article makes out a strong case for medical registration, and it is to be hoped that the General Medical Council will not object to stretch forth its powerful hand to help our brethren in the East as far as it can do so under the provisions of the Medical Act.

I am, Sirs, faithfully yours,

Otley, July 5th, 1897. R. E. WILLIAMSON, M.B. Edin.

To the Editors of THE LANCET.

SIRS,—I have read with much pleasure and interest your leading article in THE LANCET of July 3rd, dealing with the question of medical registration in India. I am sure that all who feel concerned in the well-being of our medical brethren in that country, whether British or Indian, will cordially welcome the valuable suggestions you have made with a view to dealing effectually with a much needed legislative measure, which, if carried out in some form or other, will prove a great blessing, not only to qualified medical men, but to the people of that land. Your suggestions amount to:—1. The incorporation of Indian graduates in the Colonial section of the British Medical Register. 2. A local or Indian register on the basis of the Medical Register and Directory of the Indian Empire (a compilation due entirely to private enterprise), brought out under Government authority, in which all classes of medical men in India, including the various medical subordinate services and minor grades of practitioners, should be carefully incorporated.

With regard to Indian medical graduates, the question of registration need not, as you clearly point out, involve any difficulty. Their qualifications are registrable in the United Kingdom under the Medical Act. They have but to avail themselves of the privilege of registration. But here a difficulty arises. In Great Britain and in every other British colony except India registration confers certain rights, protection, privileges, and status, for no qualified man is recognised as qualified unless his name is held on the official register. He has no legal status, he cannot claim the protection of the law courts, he cannot obtain a State appointment, and he cannot be regarded as a genuine member of the medical profession, unless his name can be found within the covers of the Medical Register. If it is honourable to be on the Register, it is akin to being dishonourable not to be on it.

Unless some such privileges are conferred on Indian graduates they can hardly be expected to indulge in the expense which registration involves. This difficulty can, however—as you further suggest—be very easily removed by a *Gazette* Order of the Government of India, promulgating a Notification that henceforth State appointments, open to

Digitized by Google

Indian University graduates in Medicine, shall be given only to duly registered candidates, and that the Government and the law courts of the country will not recognise the legal status of any but registered graduates. Such a measure would immediately settle the question of registration in India in so far as it concerns registrable diplomas. In this matter also you offer a very feasible solution to another phase of the difficulty—namely, the one of getting the General Medical Council to move in the way suggested here. Clearly the General Medical Council has a perfect right to urge the question of advancing and encouraging the registration of registrable qualifications by virtue of the fact that the Medical Act has been made applicable to India so far as registration (under the control of the Council) is concerned. May I suggest that the General Medical Council be asked to take such steps as will advance and encourage medical registration in India at its next session?

With regard to the junior grades of practitioners whose qualifications are not admissible to the British Medical Register, there is the remedy of the local register, referred to in your article; but I certainly agree with you that it is time that such powerful aid as our British General Medical Council is capable of giving to that section of our profession in India, which is entitled under the Medical Act to claim and to receive the same, should not be withheld now that the subject has received the approbation and support of the medical press in England, and the attention of our Council has thus been publicly invited to it.

I am, Sirs, yours faithfully,

London, July 4th, 1897. "FORTY-ONE YEARS IN INDIA."

THE SALISBURY TREATMENT.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers explain to me why I have received two or three letters like the enclosed asking me if I practise "the Salisbury treatment"? What is the "Salisbury treatment," and who does practise it?

I am, Sirs, your obedient servant,

THE DOCTOR OF GROSVENOR-STREET.

Grosvenor-street, W., July 2nd, 1897.

[ENCLOSURE.]

"June 26th, 1897.

"Dr. ———, Grosvenor-street.

"DEAR SIR,—I understand you recently attended a Mr. ——— and also a Mr. ———, of B———, and that you practise the Salisbury treatment. Kindly let me know if this is so and whether you could see me on Tuesday and at what time. I purpose returning to B——— on that day. I may state that I have been trying more or less strictly the Salisbury treatment, but wish before continuing it further to have medical advice as to its suitability to my case, &c. I got your name out of a Medical Directory, but am not quite sure that it is the same as mentioned by Mr. ——— at B———, not having the address by me. If it is a mistake kindly excuse.—Yours faithfully,

"A. A. A———."

"THE RECENT PRIMARY FELLOWSHIP EXAMINATION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—By the courtesy of those responsible for the management of the first examination for the diploma of Fellow of the Royal College of Surgeons of England I was permitted to be present, not for the first time, at the recent examination which is so severely criticised in the columns of THE LANCET of July 3rd. As I have been engaged in teaching anatomy for some fifteen years I may lay claim to some knowledge of the value of the examination, and as I am not, nor am ever likely to be, a Fellow of the College, I hope I may be considered to be capable of taking a perfectly impartial view of its merits and demerits. The first contention of your correspondent is that the paper questions "have about as much to do with surgery as playing the German flute has to do with learning the German language." Now, I have at hand the papers set at the last six examinations, and have been looking them through with the view of seeing how far they substantiate this startling assertion. I am bound to say that they appear to prove the opposite contention. In the last paper the pubic bone with the part which it plays in the mechanism of the pelvis, the structures between the skin and deep fascia of the lower extremity, and the topographical anatomy of the liver are surely subjects quite germane to the work of a practising surgeon. In former examinations such questions have been asked as the anatomy of the rectum from the middle of the sacrum to the tip of the coccyx—clearly with an eye to Kraske's operation—the arches of the foot and the method of their maintenance, the thyroid body, the curves of the spinal column and the movements of its various parts, the ligaments of the knee-joint, the broad ligament of the uterus, the nasal septum, the subclavian artery, the fissures of Rolando and Sylvius and their relations to the skull. Can it for a moment be argued that these questions have no bearing upon practical surgery? It would be tedious and useless to give all the questions, but a dispassionate consideration of them would, I think, show that in every case they involve facts of direct practical value, and that in no sense do they belong to the regions of transcendental anatomy. Again, your correspondent finds fault with the questions asked at the *vivâ-voce* examination. Would it be fair to inquire whether his knowledge of these questions is based upon hearsay evidence, or whether he has ever taken the trouble to find out by a visit to the examination what is the real nature of this part of the examination? From my own experience at that examination as an onlooker I can affirm that I have never heard any unreasonable question asked, nor has any question been put to a candidate which would require more than very ordinary knowledge to answer until that candidate has made it abundantly evident by his replies that he has already established his right to pass the examination.

What is required, so far as I have been able to form an opinion, is a really accurate knowledge of general anatomy, and this is precisely what most of the candidates fail to show. This is more especially the case in connexion with the subject of the bones, to which the first ten minutes or so of the *vivâ-voce* is usually directed. Surely your correspondent is not prepared to argue that the attachment of the muscles and the true position of a bone as it lies in the body are questions which should not be put to students? Yet it is precisely over questions of this kind that I have frequently seen students come to grief. Not once, but several times have I seen a candidate unable to show the examiner with any accuracy how the pelvis and os calcis lie in the body. I will conclude my remarks upon this part of the examination by affirming that I have seen and heard nothing in the anatomical part of the examination to which any fair-minded teacher of anatomy has any right to object. Your correspondent also finds fault with the physiological part of the examination, and here, as I am not a physiologist, I cannot reply with the same confidence. At the same time I may say that I have listened to the *vivâ voce* portion of the examination in this subject, and that I have not heard any questions asked thereat which in my opinion pre-supposed a greater amount of knowledge than the candidate might reasonably be expected to possess. Your correspondent's remedy is the suggestion that the examination should be postponed until a period of two years has elapsed from the taking of the Membership. He must be very ignorant of the facts of the case if he does not know that this would be tantamount to reducing the number of possible candidates by probably three-fourths. How many students are there who care or can afford to go back to the school of medicine for a winter session after having been two years qualified? And yet how few are there who, even at the time that they take their Membership, possess that knowledge of applied anatomy which would or ought to allow of their obtaining the higher diploma? Many students suppose erroneously that the same amount of knowledge which carries them through the anatomical and physiological examination for the Membership justifies them in having what they call "a shot at the Fellowship." The same kind of knowledge is required, but in the higher examination a much greater accuracy is, and in my opinion rightly so, expected from the candidate. The fact is, Sirs, that the earlier years of the student's course are so overloaded with subjects that he cannot find time for the acquisition of that amount of anatomy and physiology without which a sound knowledge of his profession is impossible. Subjects such as elementary biology, chemistry, and physics, which ought to be studied before a student enters a medical school, and materia medica, the greater part of which might with advantage be discarded altogether, are crammed into the same eighteen months, during which the student is expected to master those sciences upon which all the superstructure of his knowledge is to be erected. There is a further explanation of the large percentage of

Digitized by Google

failures which I have never seen offered, but which must be patent to all teachers of experience. Contrary to the custom with regard to the examinations for the Membership, no evidence of further study is required from candidates who have failed for the primary Fellowship before they are allowed again to present themselves for that examination. Hence we have the recurring failure of men who never go near a medical school from one examination to another, but who continue to present themselves in the hope, the forlorn hope, that by luck or by their exceeding importunity they may some day come safely through the ordeal. All teachers must know instances of such men, and all will agree that they are precisely the sort of persons who ought not to obtain the diploma of Fellow. In conclusion, may I suggest to your correspondent that he should take the trouble to visit the examination next November? If he does I venture to prophecy that he will come away with a very different opinion of it, and of those who present themselves for it, from that which he now holds. I must apologise for the length of my remarks—an answer is proverbially longer than its provocation.

I am, Sirs, your obedient servant,

July 5th, 1897. ANATOMIST.

MEDICAL HONOURS FOR INDIA.

To the Editors of THE LANCET.

SIRS,—Among the deserving members of our profession who were decorated by the Queen on the occasion of her Diamond Jubilee there was one who by an oversight was omitted from the list published by THE LANCET and by every other medical journal of this great metropolis. I refer to His Highness Sir Bhagvat Sinhjee, K.C.I.E., M.D., F.R.C.P., LL.D., Thakore Saheb of Gondal, Kattiawar, the most enlightened of all the princes of India. He was created a Grand Commander of the Indian Empire, a reward most well deserved for his unswerving loyalty to the British Crown and his beneficent rule over a contented, happy, and prosperous State.

I am, Sir, yours faithfully,

London, July 4th, 1897. ANGLO-INDIAN.

THE BATTLE OF THE CLUBS.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 54.*)

NOTTINGHAM.

Strength of the Medical Union.—Negotiations with Insurance Companies.—The Establishment of a Four-shilling Minimum.—Future Policy.

IT will be remembered that in the spring of last year the Nottingham Medico-Chirurgical Society took the initiative in forming a local medical union so as to deal with the question of club practice and other ethical and economical problems.[2] A little more than a year has now elapsed since the union was constituted, and it is satisfactory to report that great progress has been accomplished. Out of 105 practitioners in and about Nottingham 85 are in union. Nor does this mean that the remaining 20 will act in hostility to the union. At least half of the twenty are in nowise opposed to the objects of the union. They do not care to be attached to an association and to submit to its discipline. One or two have an objection—a political objection—to what appears to them in the light of trades unionism, but they are nevertheless strongly in favour of the reforms which the union strives to accomplish, and will not do anything to thwart its action. Thus, out of the 20 outsiders about half may be considered as friends, though they are not adherents; but, on the other hand, it must be recognised that some are actuated solely by interested motives. It was a remarkable fact that no sooner had the union been constituted than several young practitioners mysteriously made their appearance in Nottingham. It is alleged that they had no friends in the town, so it was shrewdly suspected that they had been induced to come to Nottingham by the insurance companies. These institutions seem to have imagined that, as a medical union had been formed, a strike against the medical aid companies would ensue at an early date, and they were anxious to have medical practitioners on the spot who could take up the work abandoned by the unionist medical men. In any case the new men arrived within a month of the formation of the union Of course, the union officials waited upon them as soon as they arrived, explained the situation, and urged that if they had not come in opposition to the interests of the medical profession they would join the union. One of the medical men in question did so at once, but three others absolutely refused, and the remainder hesitated.

The first action taken by the Nottingham Medical Union was with regard to the two great life insurance companies—the London and Manchester Industrial Assurance Company, Limited, and the Liverpool Victoria Legal Friendly Society, Limited. The former of these two insurance companies does a large business in Nottingham. It advertised its medical officers and sent out agents to tout for them. Well-to-do private patients were induced to insure their lives and obtain medical aid for which the medical men were paid only 4*s.* a year when they had been accustomed to receive the usual fees.[3] These matters were discussed by the committee of the medical union, and one of the medical officers in the service of the London and Manchester Industrial Assurance Company offered to write on his own account, but with the assent and approval of the medical union, to that company. In his letter he explained the various objections entertained by the profession and asked for alterations. In response the company sent one of their principal agents or inspectors down to Nottingham, and a conference was held between the members of the medical union committee and this agent. The agent explained the methods and policy of the London and Manchester Industrial Assurance Company, and sought to demonstrate that they were actuated by philanthropic motives, and that they worked for the benefit of the medical profession. Of course, it was objected that as they advertised and canvassed for a few medical men, to the exclusion and detriment of all the others, they could not be taken as working for the advantage of the profession as a whole. The members of the medical union committee further complained that the medical officers in the service of the London and Manchester Company only received a penny a week for the persons insured, though the latter paid three-halfpence per week. Something might be taken for the cost of collecting and managment, but a third of the total subscribed was too large a proportion, particularly as the money paid for life insurances, in which the medical officers were in nowise interested, was collected at one and the same time. It might therefore be considered that a profit was sweated out of the work done by the medical officers, both directedly—namely, the halfpenny per week per member—and indirectly—namely, the money made by the life insurances which the services of the medical officers enabled the company to effect. Then all persons insured for a sum not exceeding £20 were admitted without medical examination. The company is careful to guarantee itself against any serious loss through the ill health of its subscribers, but its medical men are in nowise protected, and in effect they are obliged to accept persons who are obviously in bad health, so long as they do not insure for more than £20. This entails a great amount of work on the medical officers, for which the penny per week paid cannot be considered anything like an adequate compensation.

In answer to these complaints the agent of the London and Manchester Industrial Assurance Company explained that though members were accepted who insured for less than £20 without any medical examination, still these subscribers had to sign a declaration to the effect that they were in good health when they first subscribed. If any medical officer could prove that this declaration was not true then the subscriber's premium would be struck off. The agent also declared that if the medical officer denounced anyone as being too rich to belong to the society, such a person would likewise be struck off the lists. Finally, the agent promised that the names of the medical men printed on the back of the company's handbills which were circulated broadcast would be removed. The distribution of these handbills constituted an advertisement, not only of the company, but also

[1] A reprint of the previous articles on the above subject has been published in book form entitled, "The Battle of the Clubs," and can be obtained from THE LANCET Office, price 1*s.*

[2] See THE LANCET, March 21st, 1896, or the reprint of "The Battle of the Clubs."

[3] See for full details THE LANCET, April 4th, 1896, and the "Battle of the Clubs" reprint.

Digitized by Google

of the medical men in its service. The bills now published no longer bear the names and addresses of the medical officers, therefore this grievance at least has been settled. The agent further promised that the canvassers or collectors of the company should no longer tout on behalf of their medical staff.

In view of all these assurances the medical union determined to defer further action in the matter for seven months. It soon, however, became evident that these promises were not faithfully kept. Practitioners wrote to the medical union to complain of the continued aggressiveness of the canvassers, and that some among them were touting on behalf of new medical men who had mysteriously appeared in the town since the formation of the medical union. Some of the medical officers in the service of the London and Manchester company wanted to resign at once, but the medical union dissuaded them because isolated resignations would be of no use, and in the face of the number of medical men imported into the town it would not be safe to proceed to extremes without careful preparations. So to feel their way the medical union invited all the medical practitioners in the town to sign the following declaration:—

"I hereby agree after June 30th not to hold office to any combined medical aid and insurance society, or to have a private medical aid which employs a canvasser; and I also agree not to meet in consultation or in any way assist professionally any medical man who is connected with such medical aids."

A large majority of the Nottingham practitioners assented to this agreement, but they were not unanimous, so that probably the work of organisation and persuasion will have to be pushed further forward before action can be taken.

Another circular, by which all the members of the profession were asked not to accept any club or contract work for less than 4*s.* per member per annum, met with a much better response. It was signed, not only by the medical union, but even by the non-unionists. Out of 110 medical men only 5 refused to sign. One of these five gave as his reason, not that he was opposed to the proposal, but that it was his habit never to sign anything. Another refused to sign because the matter did not concern him, for he had no clubs and never meant to have any, and he has kept his word. Thus it may be said that the profession in and about Nottingham is, practically speaking, unanimous in maintaining a 4*s.* minimum.

In view of a possible conflict with the insurance companies which organise medical aid for their subscribers, the medical union has discussed the feasibility of organising a public medical service to be managed exclusively by the medical men themselves. The chief objection to such a scheme was that its success would be doubtful if canvassers were not employed, and, on the other hand, the members of the medical union were much opposed to the idea of sending out canvassers. It was thought preferable to enlarge the scope and action of the existing Nottingham Provident Medical Aid Society, which is not a sweating or speculative institution, but can be considered more in the light of a charity. This society was founded in 1859, and should be almost entirely managed by medical men, but the latter have neglected their duties, so laymen had to be placed on the committee. Within the last year, and under the impulse of the medical union, a branch has been opened out in the suburb of Hyson-green, but the local medical men have failed to push this movement, so that the Hyson-green branch barely pays its own expenses. Doubtless it would be very useful if a general medical strike occurred, but if greater energy is not shown it may not live till then. This branch dispensary is also, unfortunately, situated in a back street and difficult to find.

Viewing all these facts together it must be acknowledged that the medical profession at Nottingham have set an excellent example in the formation of their medical union. The proportion of medical men who have joined as compared to the number in the town and neighbourhood is very high, and in having thus so well filled up its ranks the Nottingham Medical Union deserves the warmest praise. The Nottingham Medical Union may be felicitated, not only on its numbers and strength, but on its prudence and circumspection. Though a union to be of any service must be a fighting union, there can be no greater folly than to rush into a struggle without very elaborate and patient preparation. Now it is very evident that the Medical Union has not yet made up its mind how to act with regard to the great insurance companies. In the meanwhile there must be no isolated resignations and no individual struggles. But why attack the strongest first? Why not commence with the "sick and annual clubs" held in public-houses? That the skill of medical men should be utilised to enable a publican to sell his beer and gin is surely the greatest of all scandals, and the Nottingham Medical Union might find in these public-house slate clubs the weakest line of resistance. Certainly this grievance does not affect so large a population, but it would be better for the union to first try its 'prentice hands in a skirmish before attempting a pitched battle. Besides, in its struggle to prevent hospital abuse the union has already a very big question in hand.[4] Also a strike against the great insurance companies would disturb the habits of a large section of the population, and it is first necessary to carefully and fully inform all concerned what are the points at issue. Above all, the Nottingham Medical Union must make it very clear that it is acting in the interests of the public as well as of the profession. This can be done if enough trouble is taken; otherwise the mass of the population will certainly not understand what are the grievances. They will simply conclude that the medical men are only striving to get more money, and will probably take sides against the profession. It must, on the contrary, be rendered clear to everyone that when people who can afford to pay avail themselves of clubs, &c., intended only for the poor, this is to the disadvantage of the latter. Further, it must be shown to the rich and poor alike that everything which tends to degrade the medical profession is to the disadvantage of the entire community. The first object of a medical union should be to educate the public at large to the comprehension of these facts, and it is only when public sympathy has thus been enlisted that a big struggle may be attempted.

The joint secretaries of the Nottingham Medical Union are Mr. Paul (Derby-road) and Mr. Laws (East Circus-street), while Mr. Mackie (Shakespear-street) is secretary of the sub-committee appointed to deal with the question of hospital abuse. Dr. W. B. Ransom is the president and Dr. Mutch the treasurer of the union. The objects of the Nottingham Medical Union are: "(1) To encourage cordial relations between medical men practising in the district; (2) to give opportunities for discussion and interchange of views on the business side of medical practice; (3) to obtain the combined action and consolidated influence of members of the union upon points of difficulty which may arise in medical aid, contract, and hospital practice; and (4) generally to safeguard and support the interests of the medical profession in the town and district."

The Rules of the Nottingham Union are as follows:—

1. This society shall be called the Nottingham and District Medical Union, having for its object to safeguard and support the interests of the medical practitioners in the town and district.
2. Every registered medical practitioner shall be eligible for membership if approved by the council.
3. Each member shall pay an annual subscription of 5*s.*, due on May 1st in each year.
4. The affairs of the union shall be managed by a president, two secretaries and treasurer, and a council of fifteen members for the towns and ten for the district. Nine shall form a quorum.
5. The officers shall be elected at the annual meeting in May of each year, except that three of the town and two of the district members of the Council shall be co-opted by the Council.
6. The Council shall have power to fill up vacancies in their own body.
7. The Council shall meet once a quarter, and when convened by the hon. secretaries, to consider applications for advice or assistance, and generally to carry out the policy of the Union, and may call a general meeting of the Union at any time if considered necessary.
8. A special general meeting shall be called by the president at any time upon a requisition signed by six members, such special meeting to consider no other topic than that for which the meeting was called.
9. *No member of the Union shall oppose any practitioner in any course of action which he may take with the previously expressed sanction of the Council for the general good of the profession.*
10. Any member acting, in the opinion of a special meeting called for the purpose, contrary to the laws and regulations of the Union, shall, upon a majority of at least three-fourths of the members present, be suspended or expelled, and without appeal, from the Union.
11. A special meeting called for the purpose of considering the conduct of any member of the Union shall only be convened after fourteen days' written notice has been sent to the last-known address of each member, and such notice shall state clearly the purpose for which such meeting is convened.
12. No new law shall be adopted and no existing law shall be altered or rescinded except at the annual general meeting or at a special meeting called for the purpose, and fourteen days' notice of such proposed alterations, signed by at least three members, shall be sent to every member of the union in a circular convening the meeting.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Opening of the New General Hospital, Birmingham.

ON Wednesday, the 7th inst., amid a scene of much enthusiasm, the New General Hospital was declared open by the Princess Christian on behalf of Her Majesty the Queen. The day was observed as a general holiday in the town, and favoured by fine weather large crowds of people availed themselves of the opportunity to witness the decorations in the streets, and the preparations made for receiving the distinguished visitors. Her Royal Highness Princess Christian was accompanied by Prince Christian and the Princess Victoria. On their arrival, being met by the Lord Mayor (Councillor James Smith), a procession was formed to the Council House, where an address was read by the Recorder, expressing the deep sense of honour conferred upon the city of Birmingham by a Royal visit in the auspicious year of the Jubilee. It seemed, said the address, "most fitting that the object of the visit of Her Royal Highness should be to open one of those noble hospitals for the sick and suffering, the growth and development of which institutions constitute one of the most interesting features of Her Majesty's reign." The Princess having formally replied, luncheon was given by the Lord Mayor to a select party at the Council House. After this the procession re-formed and proceeded to the site of the new buildings, which were declared open by the Princess amid a flourish of trumpets. The senior physician and senior surgeon and the chairman of the medical committee were, among others, presented to the Princess. The Royal party returned to London by a special train at 4 45 P.M. The work of the new hospital was begun in 1892, the total cost being calculated at £210,000. The foundation-stone was laid by the Duke of York on Sept. 8th in that year. The great feature of the undertaking—one upon which the committee congratulate themselves with well-earned merit—is that it has been opened free from debt. The response made to the final application for funds has been liberal, and effectual in producing this much-desired culmination of their efforts. The hospital is replete with every modern improvement; no trouble or exertion has been spared to render every department complete. The zeal and energy of the architect, Mr. W. Henman, has been rewarded by a monument of his untiring interest and exceptional ability in providing an institution so well calculated to meet the most advanced requirements of the present age.

A Feat of Endurance.

While Princess Christian was opening the New General Hospital an athletic feat was being performed in Birmingham by a young cricket professional which would have been witnessed by many more people if it had not been contemporaneous with the royal and charitable function. Tyldesley, a Lancashire cricketer, made 100 runs in both of his innings against the home county—a feat which has only been performed by five other men, and which requires vigour, precision, and resourcefulness to a degree that can with difficulty be over-estimated.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Meeting of the Lancashire and Cheshire Branch of the British Medical Association at Owens College.

THE annual meeting of the Lancashire and Cheshire Branch of the British Medical Association was held on Wednesday last at Owens College. There was a large attendance. The retiring President, Dr. Vernon, of Southport, took the chair, and after a few words of graceful introduction gave place to Dr. S. Woodcock, the new President. Dr. Woodcock's address was listened to with great attention and many passages were warmly applauded; it dealt chiefly with medical reform. He believed that "a review of sixty years of effort and result would be more accurately expressed by the term 'miserable failure' than even by that of 'modified success.'" He spoke of the great efforts of Thomas Wakley, "the pioneer of medical reform," but said that in spite of all he did for its suppression quackery was still rampant; "advertisements imposing upon the credulity of the public appeared on the pages of nearly all our periodical literature; unqualified men practised with impunity, the present law only taking cognisance of the assumption of titles; and there were still twenty gates opening into the avenues of professional life." The Medical Act of 1886, he thought, was more entitled to attention for what it omitted than for what it accomplished. "It gave the practitioner of medicine ..... a miserably small share of representation on the General Medical Council." The accession of five direct representatives had some effect on that "lethargic body," but this was due more to the quality of the men than to their number. He criticised the constitution of the British Medical Association, and wished it, without abandoning its scientific work, to become a more efficient organisation for promoting and defending the interests of the profession. He wanted increased and improved local government, and would have all members joining the Association compelled to enter through the branches in which they practised or resided. If the nearly 35,000 members of their profession could approach agreement "they could make their own terms with Parliament," and "the end he had in view was such amendment of the Medical Acts as would afford protection both to the public and the profession." The report of the council and financial statement read by the secretary, Dr. Barr, showed the membership to be 1059—the highest number yet reached. There was a balance in hand of £394. The following appointments were approved:—President-elect, Mr. W. Berry of Wigan; vice-presidents, Mr. J. Holden and Dr. C. J. Renshaw; honorary secretary, Dr. Barr; representatives on the Parliamentary Bills committee, Dr. A. Godson, Dr. A. Brown Ritchie, Dr. G. E. Shuttleworth, and Dr. S. Woodcock. On the motion of Dr. J. B. Brierley, seconded by Dr. Holden (Preston), a resolution was passed expressing regret that the Midwifery Nurses Bill had not been carried through Parliament. The business proceedings were carried through with promptitude and so some little time was gained for the scientific work, which at these meetings is so often pushed aside in favour of warm discussions on medical politics. The dinner was attended by the Dean of the Medical Department of Owens College, the Deputy Lord Mayor of Manchester, Alderman Lloyd, and Sir Bosdin T. Leech, Dr. S. Woodcock presiding. In proposing "The Owens College and other Medical Schools," Dr. Vernon contrasted the facilities offered here for medical education in 1848 with the present magnificent school, "where there were 400 students gathered under one roof and taught by professors of European reputation." Professor Delépine responded. Mr. W. Berry, president-elect, proposed "The Branch and its Office Holders," to which Dr. Barr responded.

The St. John Ambulance at the Royal Agricultural Show.

What with the Jubilee celebrations, into which Manchester entered with enthusiasm, the Royal Agricultural Show at Old Trafford, and the visit of the Duke of York, there has been enough to break through the ordinary routine of life in this busy commercial centre. For the last few years the St. John Ambulance Association has had a well appointed hospital at the Show. This is due to the indefatigable energy of Surgeon-Major Hutton, who was on the ground the whole time. He was ably assisted by Surgeon-Captain Darwin, M.D., 2nd V.B. M.R., and Surgeon-Captain Fairclough, M.D., V.M.S., two St. John nurses, and seven St. John Ambulance Brigade men, under the supervision of Mr. Superintendent Goodwin, and most valuable first aid has been given. Besides numerous minor cases, as burns, scalds, cut fingers, sprains, faints, &c., several serious cases were attended to, and then removed to the Salford Hospital. When H.R.H. the Duke of York paid a special visit of inspection yesterday week, he seemed much pleased with what he saw, and said a few kindly words to the patients.

The Explosion at a Chemical Works.

At the adjourned inquest respecting the deaths of two men from the explosion mentioned in my last communication some light was thrown on its cause. The still was charged with about twenty tons of coal tar, which was added to about ten tons of oil, which had been left after an oil-distilling process thirty-six hours previously. The engineer said that after the fire was lighted, about 8 A.M., he saw Duddle, one of the men killed, who said the still "was going on all right." He thought the explosion must have

Digitized by Google

been due to a block in the coil or in the pipe leading from the still. In answer to Mr. Rogers, factory inspector, the witness said they took no steps to ascertain that the courses were clear before charging. The manager of a branch works said there was only one possible explanation—a blocking of the coil or a stoppage of the pipe between the still head and the condenser, which, in his opinion, could have been discovered before the explosion. The verdict was that the explosion was due to the accidental stoppage of the worm. Mr. Rogers said that he would make recommendations "in the direction of seeing that the pipes and passages were clear before the commencement of operations." The coroner made the very sensible remark that "it was not sufficient to say to men that they must do this or that; it was better to require them to make an entry in a book certifying that they had done it."

July 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Society of Edinburgh.

AT the meeting of the Royal Society of Edinburgh, held on Monday, July, 5th, Professor Fraser made a further communication on antidotes for snake-bite, the title of his communication being "The Anti-venomous Properties of the Bile of Serpents and other Animals, and an Explanation of the Insusceptibility of Animals to the Poisonous Action of Venom introduced into the Stomach." He had made experiments with the bile of the African cobra, the puff-adder, the rattlesnake, and the grass-snake, testing them against the venom of the African and the Indian cobra. Rabbits were used for the experiments. The results showed that the bile of venomous serpents when mixed with venom prevented lethal doses of the latter from producing death. A quantity of bile smaller than the amount of venom was sufficient for this purpose. Bile introduced hypodermically was itself poisonous, but he had succeeded in separating from the bile its antidotal constituent. He had experimented with this, and there was strong evidence to show that not only was bile able to render serpent's venom inert, but also to suggest that from bile there might be produced an antidote for snake-poisoning which was at least equal to the most powerful anti-venene or anti-venomous serum obtained from immunised animals.

Convalescent Home for the Victoria Infirmary, Glasgow.

The directors of the youngest of the Glasgow general hospitals have never been wanting in the enterprise and energy necessary to secure the reputation and practical success of the institution under their care. In many respects a model infirmary, the Victoria has now acquired the valuable complement of a convalescent home. The home, which is situated at Largs and will accommodate forty patients, was opened on June 27th by Sir Renny Watson, the chairman of the infirmary. Among those present were Professor Gairdner, Dr. Ebenezer Duncan, Dr. Alexander Napier, Dr. A. E. Maylard, and Mr. R. H. Parry. The total cost of the home and grounds has been £5000.

Glasgow University.

The clinical portion of the final examination for degrees in medicine and surgery has now been completed, and the written examinations commence to-day. The "orals" will continue for the greater part of the month, and the graduation ceremony is fixed for the 22nd inst. The medical classes closed for the summer session on the 25th ult. The prizes awarded by the directors of the Ear Hospital for competition among the students attending Dr. Barr's class have been gained by Mr. J. B. Miller and Mr. David Sloan Harvey. At the June meeting of the University Court sketch plans for the new botanical and engineering laboratories to be placed on the frontage of the university avenue near the gymnasium were submitted. The court approved of the report which had been adopted by the General Medical Council in reference to the powers of sanitary inspectors under the Public Health (Scotland) Bill, and ordered copies of their decision to be forwarded to the Lord Advocate and others.

Handsome Donations to Glasgow Charities.

In commemoration of the Queen's Diamond Jubilee ex-Lord Provost Sir James Bain has given the sum of £3000 to various medical institutions in Glasgow. The Royal Infirmary receives £1000, the Western Infirmary £750, and the Victoria Infirmary £500.

Insanity in Scotland.

Mr. John Carswell in his annual report as certifying physician in lunacy to the Glasgow Barony Parish Council, again notes an increase in the number of persons placed on the lunacy roll. The number for the last year was 263, as compared with 237 in the preceding year. Mr. Carswell, however, argues against the conclusion that these figures justify the view that lunacy is increasing. He states that in his district imbecile children are placed on the list of registered lunatics, and notes a greater tendency on the part of guardians to apply to the inspector in connexion with weak-minded children. In a similar manner he observes that there is less reluctance than was formerly the case to place elderly persons who have become "weak-minded" under asylum treatment. In this way the increased numbers on the lunacy roll are at least largely explained. Mr. Carswell allows that there has been a considerable increase in the number of patients suffering from general paralysis, but even here he declines to adopt pessimistic views, and expresses an opinion that the cause of the increase is a "temporary" one.

St. Andrew's Ambulance Association.

At the annual meeting of the members of this association, held in Glasgow on June 30th, it was decided, on the motion of Dr. George T. Beatson, to make application for incorporation by Royal charter, and a committee was appointed to carry this resolution into effect.

Proposed Memorial to William and John Hunter.

The movement so energetically promoted by the late Dr. Mather is now taking definite shape, and at a recent meeting in Glasgow, summoned by a circular signed by the Lord Provost, the Principal of the University, and the President of the Faculty of Physicians and Surgeons, an executive committee was appointed to collect subscriptions; it is hoped that from £3000 to £4000 may be raised. Dr. Oswald Fergus was appointed secretary to the executive committee. It was intimated that Mrs. Mather has a sum of £850 which she is willing to add to the fund now proposed to be raised.

July 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mercer's Hospital.

AT a meeting of the governors of this institution, held on July 6th, the following were elected physicians to the hospital:—Mr. E. Ledwich and Dr. J. Lumsden. The surgeons elected were as follows:—Dr. Montgomery Ward, Mr. J. D. McFeely, and Mr. Henry Moore. Dr. E. Stamer O'Grady, a member of the former surgical staff, entered a protest against the proceedings on the ground that "there was at present a sufficient surgical and medical staff in the hospital." The Rev. Dr. Tisdall also handed in a protest against the proceedings. It will be noticed that Dr. Montgomery Ward was the only member of the old staff who has been re-elected.

Vaccination in Belfast.

At the weekly meeting of the Belfast Board of Guardians, held on June 29th, a letter was read from the Local Government Board enclosing extracts from a report of their inspector, Dr. Clibborn, which pointed out that, taking Belfast and Castlereagh dispensary districts together, there were over 600 children who seemed to be unprotected by vaccination. A committee was appointed to inquire into the matter.

The Infectious Diseases Hospital, Belfast.

The public health committee of the Belfast Corporation have recommended that the Local Government Board be requested to give their sanction to the council's borrowing £20,000, being the amount estimated as being required for the erection of an infectious diseases hospital, containing between sixty and eighty beds, capable of extension as may be required from time to time, on the site already approved by the council at Purdysburn. This matter will come up on

Digitized by Google

July 15th at the Local Government Board inquiry to be held in Belfast on that date.

The Royal Victoria Hospital.

The sum (£100,000) aimed at as the amount required by the promoters for the building fund of the new Royal Victoria Hospital having been subscribed, it has been decided that any further sum will be placed to the credit of the endowment fund, and already a considerable amount has been acknowledged.

Belfast Asylum.

Dr. Merrick, the resident medical superintendent of the Belfast Asylum, has resigned his post. He has been a most capable and efficient administrator, and it is a source of great regret to his friends that his state of health obliges him to retire.

Sudden Death of a Cork Medical Man.

The members of the medical profession in Cork experienced a painful shock last Sunday on learning that Dr. Michael J. Murphy had died suddenly. Dr. Murphy was a man of splendid physique, only about thirty-three years of age, and, as far as his relatives and friends knew, had enjoyed excellent health. Last Saturday he discharged his professional duties with his usual energy. The following morning his sister, noticing that he had not come downstairs, entered his room, and, failing to arouse him, became alarmed. She at once sent for medical aid, and two medical men were promptly in attendance, but only to find that he had been dead for some hours. Dr. Murphy was an enthusiastic bicyclist, and it is believed he suffered from some latent form of heart disease, which became aggravated by over-exertion. He had a distinguished collegiate career, and graduated at the Royal University in the year 1886. Soon afterwards he was appointed resident physician to the Cork Union Hospital. He resigned that position in 1892, and was elected consulting sanitary officer to the Cork Union. During the past four years he was one of the physicians of the Mercy Hospital, and had established a reputation as a clinical teacher. Some few years ago he was unanimously elected honorary treasurer of the Cork Medical and Surgical Association, and his genial, unobtrusive manners made him a great favourite with his professional brethren.

Some Cases of Typhus Fever in Cork.

At a meeting of the public health committee of the Cork Corporation, the medical general superintendent of health reported an outbreak of typhus fever in a few tenement houses in the city; twelve of the inmates were attacked and were promptly removed to the Union Fever Hospital. The houses were disinfected, and other measures adopted to prevent the spread of the disease. Some twenty-five years ago the occurrence of typhus fever was tolerably common in the city, but, thanks to improved sanitary conditions and to the greater facilities for grappling with it at once, it has become a rare disease in Cork—so much so that many of our younger medical men have probably never seen a case.

July 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Resection of the Cervical Sympathetic.

TWO cases of resection of the cervical sympathetic for exophthalmic goitre have just been published by two surgeons, and each operation has resulted in complete success. The first case was reported to the Academy of Medicine by M. Reclus, and the operation was performed by a young surgeon, M. Faure. The patient was a woman, aged twenty-one years, who developed exophthalmic goitre after her third pregnancy. She suffered from salivation, polyuria, crises of diarrhœa, marked tremblings, sensations of heat and cold, feebleness of the legs, very marked exophthalmos, and tachycardia. Electrical treatment brought about some amelioration of the symptoms, but soon all the phenomena reappeared. The eyelids failed to cover the eyes and corneal ulceration commenced; the thyroid was enormously hypertrophied, the apex beat so markedly as to raise the chest wall, the pulse-rate increased from 120 to 130, and her hair began to fall off. At length the presence of tuberculous masses in the neck and chest was clearly to be made out. M. Faure accordingly performed the following operation after the method laid down by M. Jaboulay, of Lyons. An incision twelve centimetres long was made on the right side of the neck just behind the sterno-mastoid muscle, the cervical branch of the spinal accessory was divided, and the superficial and deep cervical plexus came into view. The vascular and nervous structures lying in front of the vertebral column were separated and pulled forwards, and behind them the great sympathetic came into view. The superior cervical ganglion was picked up and the afferent branches as far as the middle ganglion removed. Then some seven centimetres of the great sympathetic were resected. A similar operation, but complicated by the removal of some tuberculous glands, was performed upon the left side. During the operation there was no change noticeable in the pulse or in the condition of the thyroid, but by the evening the pulse was less rapid and the patient slept. On the seventh day after the operation the exophthalmos was much less, and, the patient being able to close her eyes, the corneal ulcers began to heal. The circumference of the neck had diminished from 39 centimetres to 36; the pulse-rate had fallen to 90; and the tremors, the salivation, and the diarrhœa disappeared. The second case was reported to the Academy of Medicine at the next meeting by M. Gerard Marchant. The patient was a woman with a neurotic family history. In March, 1896, exophthalmos appeared after a pregnancy, in August thyroid hypertrophy commenced, and in January, 1897, tremors. The exophthalmos was extreme and the eyelids did not cover the eyeballs. The goitre was specially marked on the right side. The pulse-rate was 80 while the patient was at rest and became 100 on moving. The heart was normal, and at this time the tremors were well marked. M. Marchant then operated. An incision was made in the line of the sterno-mastoid muscle, the various vascular and nervous structures were lifted up, and the great sympathetic was found lying on the deep muscles of the neck. To make certain, the nerve was exposed as far as the superior cervical ganglion. Four centimetres of the nerve were then resected from above the superior ganglion to below the level of the middle ganglion, which is often absent. The nerve was cut on each side successively. The operator began on the left side, and a sub-conjunctival ecchymosis appeared in the right eye, due probably, as in the experiments of Dastre and Morat, to excitation of the central end of the nerve by the forceps. After the operation the pupils contracted, the eyeballs diminished, and the goitre disappeared by about the twelfth day. Later, some of the phenomena returned in a much less marked form, but still obvious. As M. Marchant says, there is still much to be learned.

X Rays in the Diagnosis of Thoracic Affections.

MM. Beclere, Oudin, and Barthelemy have recently shown at the Hospitals' Medical Society a series of most interesting x ray photographs, forming the best results hitherto obtained in France. The first two photographs were taken from the same patient, a man affected with a large pleural effusion on the left side, one print being obtained before and the other after thoracentesis. The difference between the opacity of the fluid and the transparency of the lung tissue after paracentesis was well shown. The photographs also show that in this patient, aged sixty-six years, the thoracic aorta at its junction with the arch is somewhat dilated and bulges towards the left of the vertebral column just at the level of the fifth dorsal vertebra, a condition observed before by radioscopy to be more or less pronounced in those subjects whose peripheral arteries are hardened and tortuous. Another print showed the thorax of a child suffering from a tuberculous affection of the tracheal and bronchial glands, and made it evident that besides the retro-sternal mass, which is alone capable of diagnosis by the ordinary means, there existed, also deep in the substance of the two lungs around the roots, numerous other masses, and that on the right side they extended along the various ramifications of the bronchi. In another case, that of a patient with pyo-pneumothorax, the level of the effusion was plainly seen as well as the shrunken lung, and the bodies of the vertebræ, together with an apical adhesion. The left lung, which appeared sound to auscultation, showed by the x rays a multitude of opaque patches due doubtless to scattered masses of tubercle. In another case, that of a young girl whose chest had been carefully examined by

Digitized by Google

M. Rendu, and in whom only very indefinite results had been obtained, the x ray photograph showed a dark patch at the apex of the lung and another at about the middle.

Quackery at Angers.

The tribunal of Angers have just decided that a man named Mouroux, who set up as a magnetiser, cannot be proceeded against under the law to restrain unqualified medical practice. The Syndicate of Medical Men at Angers have accordingly appealed against this judgment.

The Manufacture of Theses.

A political journal has just started an active campaign on the subject of theses for the degree of doctor of medicine, which some students buy all ready written from their companions. Latterly this occupation has become a real industry, and a library has had the impertinence to send round among the students a regular prospectus, which runs as follows: "This house will supply manuscripts for a thesis to any candidate who will apply for one." The editor of the journal in question having read this went to the library as a student and commenced negotiations for the purchase of a thesis. He was offered an excellent ordinary thesis "for 200 francs; for one still better 500 francs was asked; and for one of the very first class," about which everyone will talk, 1000 francs. The journalist asked for a very ordinary and short thesis and obtained a decrease in price of 150 francs. The story, which is probably exaggerated, has greatly excited the lay public, and has given an additional argument to those who are agitating for doing away with the thesis altogether. As a matter of fact, however, the only new features are the effrontery of the library and its prospectus. There are always some theses written by needy and clever young men for medical men who have to get through their studies quickly so as to return to the district where they mean to practise; and, in addition, foreign medical men often find it impossible to write a long medical treatise in really good French, and often have to get the help of the residents at the hospitals, who are always willing to make a little money in this way. As a fact, these theses are very often better than those which the candidate has written himself, and which the Faculty has nevertheless accepted.

July 5th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Brazilian Government and the Bacillus of Yellow Fever.

NATURALLY enough Dr. Sanarelli's discovery of the bacillus icteroides awakens the keenest interest in the South American communities, where, according to Dr. Jacopo Mantegazza (in a letter to a Tuscan contemporary written just after his return last week from Rio Janeiro), a concurrent series of investigations by the Brazilian Dr. Felipe Caldas goes far to confirm the findings of the Sienese pathologist. With a view, it would appear, to a final judgment on these findings, a Bill just brought before the Brazilian Legislature and now agitating the Chamber of Deputies at Rio, "offers a prize of 400 contas de Reis (£44,000), divided into two equal parts, first to the author of a work demonstrating the existence of the bacillus icteroides and the surest and readiest means of its bacteriological diagnosis; second, to the discoverer of the effective clinical treatment of the bacillus so ascertained, and of the best prophylactic mode of dealing with it. The court of adjudication by which the prizes are to be awarded shall consist of the Medical Institute of Rio Janeiro, the Koch Institute at Berlin, and the Pasteur Institute at Paris. Another provision of the Bill authorises the Government to reserve the sum of 200 contas de Reis for the founding of an establishment for the preparation of the serum destined to antagonise the bacillus of yellow fever, and conceding to the discoverer of the serum in question the organisation of the serotherapeutic institute established *ad hoc*. Dr. Mantegazza concludes his letter with the remark that in Brazil the award of the prize (or rather prizes) to Dr. Sanarelli is considered a foregone conclusion. All the same, the action of the Brazilian Government in making its legislative recognition of the "bacillus icteroides" contingent on the confirmatory verdict of its own highest professional tribunal, sustained by the Koch and Pasteur Institutes, is both reasonable and right.

Another "Incredible Scandal."

In THE LANCET of June 12th I drew attention to the maladministration of the Foundling Hospital at Naples, by which, in two years, out of 856 admitted only three of the little inmates survived, and I remarked that the Neapolitan institution was but a specimen—"though an exceptionally ghastly one"—of the many establishments of the kind in the great cities. Now Venetia, as the result of recent inquiries, claims the second place after Naples for its "slaughter of the innocents." A Paduan correspondent says: "The eight provinces making up the Venetian territory (Verona, Vicenza, Belluno, Udine, Venice, Rovigo, and Treviso), occupying a superficies of 24,000 square kilomètres, and having a population of nearly three million inhabitants, send annually to their respective 'Brefotrofi' (foundling hospitals) a mean of 140,000 infants, the vast majority (it need hardly be said) illegitimate. The mortality among them is 52 per cent.—rather more than half—the cause of this frightful death-rate being, primarily, want of sufficient nourishment, and, secondly, neglect of every description. To attain this result, the hospitals in question spend every year 15,000,000 francs derived from the bequests of benefactors and the contributions of the provinces and communes." Padua is prominent for the death-rate of the infants in her "Brefotrofio," and what wonder when in that establishment one wet-nurse is expected to give the breast to two, and even three, babes per diem? In Naples, it will be remembered, the same wet nurse suckled from three to four a day.

The Boycotting of British and American Practitioners.

In the Chamber of Deputies on the 3rd inst. Dr. Santini, promoter of the Bill to exclude English-speaking medical men from practising in Italy, asked what were the intentions of Government as to Article 23 of the "Legge Sanitaria" which he proposes to modify in the above sense. Signor Serena, on behalf of the Government, replied that medical practitioners of non-Italian nationality would be allowed to practise among Italians in Italy if Italian medical men had the same privilege conceded them by the other nationalities in question. Signor Serena added that Article 23 of the "Legge Sanitaria," still in force, allowed foreign medical men to practise among their compatriots resident in Italy if they did not extend their *clientèle* to Italians. The abuse of this privilege (he said) the Government had hitherto guarded against, and would, he added, continue to guard against, with increased vigilance. This did not satisfy Dr. Santini, whose object is to confine English-speaking practice in Italy to Italian practitioners, and to make it as impossible for British or American medical men to pursue their profession among compatriots in the kingdom as it is now in Switzerland and France. Manifestly, this was more than the Government, represented by Signor Serena, were prepared to grant. As THE LANCET has pointed out, the presence of the English-speaking colony in Italy is (to Italy) so pecuniarily important that any legislation calculated to deter or even diminish it would on Italy's part be distinctly suicidal; and the legislation sought by Dr. Santini partakes of that character.

July 4th.

THE LIFE SAVING SOCIETY: A SUCCESSFUL FETE.—During the six years of its existence the Life Saving Society has organised no such important gathering as that of the "Diamond Jubilee International Gala," which took place at the West India Docks on Saturday afternoon last. The gala had been timed to commence at 3 o'clock, but long before that hour spectators began to occupy every coign of vantage from which a view of the proceedings, however limited, was obtainable. The dock was gaily decked with flags, and a most enthusiastic welcome was given to H.R.H. the Duke of York, the President of the society, who arrived punctually at the appointed hour of 3 o'clock, accompanied by the Duchess. The programme was then gone through without a hitch. The most important event, the mile amateur championship, was secured by J. A. Jarvis, of Leicester, who is reported to have raced untrained, but the diving exhibition of the Swedish representatives was the most popular item on the card. The Hon. Sydney Holland presided over the festival dinner of the society which followed at the Holborn Restaurant.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, have been admitted Licentiates in Dental Surgery:—

Ackland, Donald, Charing-cross and the Dental Hospital of London.
Arnold, John Cressey, London Hospital and the National Dental Hospital.
Austen, Harold William Colmer, M.R.C.S. Eng., St. Bartholomew's and the Dental Hospital of London.
Bell, Robert John, Charing-cross and the Dental Hospital of London.
Brown, Charles Every, Guy's Hospital.
Brown, Ernest Chodwick, Guy's Hospital.
Brown, James Warburton, Charing-cross and the Dental Hospital of London.
Canton, Loftus Henry, Middlesex and the National Dental Hospital.
Coates, Frederick Arthur, University College.
Cook, Percy Herbert, Guy's Hospital.
Cooper, Albert, Guy's Hospital.
Cooper, Percy Henry Rogers, Charing-cross and the Dental Hospital of London.
Douglas, James Carfrae, Charing-cross and the Dental Hospital of London.
Duncan, Frank Hubert, Charing-cross and the Dental Hospital of London.
Everett, Charles, Middlesex and the National Dental Hospital.
Floyd, Walter, Guy's Hospital.
Forsyth, William Frederic, Charing-cross and the Dental Hospital of London.
Harrison, Sydney, Guy's Hospital.
Heath, Arthur Reginald, Charing-cross and the Dental Hospital of London.
Hey, Stephen Daniel, Charing-cross and the Dental Hospital of London.
Holmes, Robert Gabriel Stuart, Guy's Hospital.
Jacobs, Jacob Michael Cecil, Guy's Hospital.
Jones, William Henry, Middlesex and the Dental Hospital of London.
Lees, Charlie, Charing-cross and the Dental Hospital of London.
Lishman, James, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester.
North, Benjamin, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester.
Oddy, Alfred Ernest, Guy's Hospital.
Picnot, Ernest, Guy's Hospital.
Poundall, Alfred Ben, Middlesex and the National Dental Hospital.
Powell, Matthew Pearce, Charing-cross and the Dental Hospital of London.
Reading, George Frederick, Charing-cross and the Dental Hospital of London.
Robertson, Arthur Edwin, St. Bartholomew's and the National Dental Hospital.
Robinson, Robert Percy, University College, Royal Infirmary, and the Dental Hospital, Liverpool.
Rogers, David de Sola Cohen, Charing-cross and the Dental Hospital of London.
Roper, John Langdon, Middlesex and the Dental Hospital of London.
Rowe, William Francis, Charing-cross and the Dental Hospital of London.
Sadler, Bernard Frederick, Mason College, Queen's and General Hospitals, and the Dental Hospital, Birmingham.
Shedden, Arnold Ward, Mason College, Queen's and General Hospitals, and the Dental Hospital, Birmingham.
Smart, Edwin Herbert Jacob, Charing-cross and the Dental Hospital of London.
Smith, Edward Percy, Charing Cross and the Dental Hospital of London.
Smith, Edwin Wylde, Guy's Hospital.
Smith, Thomas William, Charing-cross and the Dental Hospital of London.
Stoner, John Walton, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester.
Styer, Albert St. John, Guy's Hospital.
Summers, Gilbert Hamilton, Charing-cross and the Dental Hospital of London.
Thew, Thomas Wilton, Middlesex and the Dental Hospital of London.
Tidswell, Oswald, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester.
Wallis, Charles Edward, M.R.C.S. Eng., King's College and the Dental Hospital of London.
Wallis, Elton George Whishaw, Guy's Hospital.
Westron, Henry, Charing Cross and the Dental Hospital of London.
Williams, Sidney Herbert, Charing-cross and the Dental Hospital of London.
Willis, Stuart, Mason College, Queen's and General Hospitals, and the Dental Hospital, Birmingham.
Wilson, Charles Albert, Guy's Hospital.
Wilson, George Edward, Charing-cross and the Dental Hospital of London.
Woodhouse, William Barnabas, M.R.C.S. Eng., Middlesex and the Dental Hospital of London.

Fourteen gentlemen were referred back to their professional studies for six months.

The following gentlemen, having previously passed the necessary examinations and having now conformed to the by-laws and regulations, have been admitted Members of the College:—

Dantes, Augustus Paul, L.M. & S. Bombay, Grant Medical College, Bombay, and Charing-cross Hospital.
Gandier, Augustine, M.D., C.M. Kingston, Queen's University, Kingston, Canada, and Middlesex Hospital.

ROYAL INSTITUTION.—At the general monthly meeting of the members of the Royal Institution, held on Monday, July 5th, Sir James Crichton Browne, M.D., F.R.S., treasurer and vice-president, presiding, the special thanks of the members were given to Sir Andrew Noble for his donation of £100 to the Fund for the Promotion of Experimental Research at Low Temperatures.

THE PROPOSED CONVALESCENT HOME FOR BRISTOL.—The progress of the fund for providing a convalescent home for Bristol has not been quite equal to the anticipations of the proposers of this scheme. According to the list published on June 26th, the unconditional subscriptions are under £18,000; £50,000 is the sum required. There are also conditional promises of £7446; £20,000 has been raised for an endowment fund conditional upon the sum of £50,000 being first raised.

PRESENTATIONS TO MEDICAL MEN.—Mr. F. E. Haydon, M.B. Glasg., L.R.C.P., L.R.C.S. Edin., of Littlehampton, has been presented by the local ambulance class with the two volumes of Nansen's book, "Farthest North," and also a silver-mounted umbrella, in appreciation of his services as honorary lecturer to the class.—Mr. R. A. Prichard, M.R.C.S. Eng., L.R.C.P. Edin., of Conway, has been the recipient, from the Conway ambulance classes, of an honorary Life Certificate, in recognition of his instructive lectures on First Aid.

MR. LEWIS A. TALLERMAN has presented the North-West London Hospital with a Tallerman-Sheffield apparatus for the localised application of super-heated dry air. We understand that this present was made in response to a request from the secretary of the North-West London Hospital to be allowed the free use of the apparatus under hire at the hospital at the time as a Jubilee donation, and that Mr. Tallerman is willing to extend the same generosity to five other hospitals if applications are made to him at 50, Welbeck-street, Cavendish-square, W.

THE POPLAR HOSPITAL FOR ACCIDENTS.—The annual dinner of the supporters and friends of this charity was held for the forty-second time on June 29th at the Holborn Restaurant. Mr. Thomas Catling was in the chair. The chairman, in proposing the toast of the evening, "Success to the Poplar Hospital," referred to the good work which the hospital had carried on during the forty-two years of its existence. The Hon. Sydney Holland, the energetic former secretary, who responded to the toast, said that in the six years previous to 1890 they received from the public £23,000, but in the six years ending 1895 they had received no less a sum than £60,000. Subscriptions amounting to £1650 were announced.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting of this society was held on June 30th, Dr. J. F. Payne, President, being in the chair.—Several interesting cases were brought forward by Dr. Abraham, Dr. Savill, and others.—A case of Multiple Lupus in a little girl, six years of age, shown by Dr. Abraham, excited much comment. There were a dozen or more isolated tuberculous-looking nodules about the size of a pea, or a little larger. There were a few scattered nodules about the body generally and the limbs. Slight enlargement of the lymphatics, of the axillæ, and of other regions was noticed.—Dr. Payne considered the possibility of the lesions being those of congenital syphilis. The child had a swelling of one of the finger joints, (?) "strumous dactylitis." The mother gave a history of several miscarriages.—Dr. Abraham promised to examine the growths. The nodules had existed in their present condition for about a year, and it was stated by the mother that they all "came out at once."—Dr. Ryan showed a case of X Rays Dermatitis; the skin of the shoulder and bosom was affected; exposure forty-five minutes. The photograph had not been successful. Hair was still growing over part of the affected region.—Mr. Pernet stated that he knew of a hairy mole which had been subjected to an exposure of [illegible] without destruction of the hair follicles hav[illegible]

MEDICAL MAGISTRATE.—His Excellency the Governor of New South Wales has appointed Mr. Thomas Arthur Grieves, L.R.C.P. Lond., M.R.C.S. Eng., of Wyalong, New South Wales, a magistrate for that colony.

MR. RUDYARD KIPLING'S "Our Lady of the Snows" and "Hymn before Action" have been set to music, and will be sung by special permission for the first time at the musical conversazione arranged by Miss Janotha to-day (Saturday), "Queen's Day," in the National Hospital for the Paralysed and Epileptic, Albany Memorial, Queen-square, Bloomsbury.

THE DWELLINGS OF THE POOR.—The report of the Mansion House Council for the year ending Dec. 31st, 1896, states that in presenting its thirteenth annual record of work done to further the interests of sanitation in London and the suburbs the council feel that there is even a stronger necessity than in the past for keeping a steady watch upon the work of the local authorities, upon whom is devolved the serious responsibility of making and keeping their various districts in sound sanitary condition. During the past twelve months 10,684 inspections dealing with 7545 houses in all parts of London have been made. Of these the defects have been remedied in 3624 cases, while 2108 are still under consideration, and 1813 have been dismissed.

THE NATIONAL ASSOCIATION OF MASTER PLUMBERS.—The annual meeting of the London branch of the above association was held on June 29th, followed by a dinner at the Holborn Restaurant. Though the matters discussed were devoid of any general interest, yet such associations must have a very pronounced influence for good, if an indirect one, upon the sanitary condition of the community. It is understood that this association does not exist simply for the purpose of benefiting the masters alone, but extends its operations to the improvement of the status of the trade as a whole. One object is to establish boards of conciliation, composed jointly of masters and operatives, in order to promote a better general understanding, and arrive at an amicable settlement in any matter of dispute.

EAST SUFFOLK AND IPSWICH HOSPITAL.—The anniversary Court of Governors of this institution was held at the town-hall on Wednesday, June 30th, when the chair was occupied by the Mayor. A most satisfactory report was unanimously agreed to. It was shown that the work of the hospital had considerably increased, the number of in-patients being augmented by 48 and the out-patients by 1191. The expenses, however, had been reduced. Considerable discussion took place on a resolution proposed by the Mayor to the effect that it is desirable that the secretary should devote his whole time and attention exclusively to the affairs of the hospital, and that he should reside within the hospital, unless specially exempted from so doing by the committee of management. Eventually it was decided that the board of management should consider and report upon the matter.

DIPHTHERIA IN LONDON.—In the four-weekly period ended with June 19th the notified cases of diphtheria in London were much in excess of the total of the preceding like period ended on May 22nd. In the May period the total was 777, yielding a weekly average of 194, all the sanitary districts except two being invaded. In the June period the like number of sanitary areas were invaded, but the total of notifications reached 895, a number which yields a weekly average of 224. In May only one district had upwards of 50 cases notified; in June two districts were so circumstanced, with an aggregate of 141 notifications. Other five districts in June had only 17 notified cases in all. In the May period the registered deaths from the disease in London numbered 142, a weekly average of 35, with a resulting per case mortality on notifications of 18·3 per cent. In the June period the deaths fell to 137, or 34 weekly; and in the circumstance of an increased amount of disease the per case mortality rate fell to 14·1 per cent. Thus, whilst in the June period the quantity of diphtheria prevalent was in excess of the four preceding weeks, the nature of the malady, as judged by the mortality data for the corresponding weeks, was milder. Compared with the June period of 1896, the current year's data show favourably. In 1896 the cases amounted to 1060, or 265 weekly; the deaths to 196, or 49 weekly; and the per case mortality rate was 18·5 per cent. In the two weeks of the current year completed since June 19th the deaths from diphtheria in London have been 24 and 32 respectively. The latter total during last week was 3 below the corrected decennial average for the twenty-sixth week of the years 1887–96. Three deaths belonged to each of the following sanitary areas:—Battersea, Camberwell, Chelsea, and Lambeth. Two of the 32 deaths were of persons aged upwards of 20 years, and 3 were of infants. Last Saturday found 869 diphtheria patients still under treatment, the admissions during the week having been 152. In the outer ring, only 5 deaths were registered from diphtheria last week, namely, one in Chiselhurst, Chiswick, Barnet, Hornsey, and Enfield districts respectively.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JULY 1ST.

Classification in County Asylums.

MR. WEIR asked the President of the Local Government Board whether it was the practice within the metropolitan area to classify as paupers patients who were under treatment in county asylums, notwithstanding the fact that the cost of maintenance was provided by the relatives or friends of the patients; and, if so, whether it was proposed to take any steps to amend the present system of classification.—Mr. Chaplin replied that he was informed that all patients in county asylums were classed as paupers whose maintenance was paid for by the guardians, although it might be that in some cases the guardians were partially recouped by sums received from relatives. He had no information which would lead him to think that a grievance existed, but he would make further inquiry.

Ventilation of the Metropolitan Underground Railways.

Mr. Ritchie, in reply to Mr. Weir, said that the Committee on the Ventilation of the Tunnels of the Metropolitan and Metropolitan District Railways hoped to conclude the taking of evidence on July 6th. They had arranged to visit the Severn Tunnel to inspect the ventilating arrangements on July 12th, and the report would be made as soon as possible after that date.

Poona Plague Administration.

Lord George Hamilton answering questions on this subject said that the measures taken at Poona to prevent the spread of the plague had been attended by a remarkable amount of success, the deaths from plague having fallen from 177 per week to 7 per week within the last two months. While that was so they had been the subject of much misrepresentation and exaggeration in a portion of the vernacular press. He was confident that the Governor of Bombay had been and was most careful to confine the action of the authorities to what was absolutely necessary for checking the plague, and to show all possible consideration to the religious opinions and customs of the inhabitants. He had no reason to think, as at present advised, that any inquiry into the administration of Poona during the plague was necessary or desirable.

Indian Famine Statistics.

Lord George Hamilton said, in reply to a question, that the Indian Government had reason to believe that deaths were frequently reported as due to starvation when they were really due to other causes, and had in consequence issued orders to prevent the famine statistics from being vitiated by inaccuracies of this kind.

FRIDAY, JULY 2ND.

Viewing the Body at Inquests.

Mr. Yoxall asked the Secretary of State for the Home Department if his attention had been drawn to the fact that jurymen at coroners' inquests often took grave objection to the statutory task, always unpleasant, and frequently repulsive or dangerous, of viewing the body, and if he would consider the subject in order to devise some alternative method, leaving the coroner or jury to decide in difficult cases whether such viewing was necessary, and abolishing such viewing in ordinary and well-attested cases where the medical evidence was conclusive.—Sir Matthew White Ridley said, in reply: Yes, objection is taken occasionally, I believe, to the performance of this duty, and the question of relaxing the requirement was some years ago under the consideration of this House. I am afraid there is no prospect of my being able to deal with the matter at present, even if it should appear on consideration to be desirable to do so, but I will look into it and ascertain from the coroners what views are held by them upon the subject.

MONDAY, JULY 5TH.

Cattle Disease.

Sir Arthur Forwood asked the President of the Board of Agriculture whether British steamers which call at Havre to receive cargo on their outward voyage for America were precluded from conveying from America to England live cattle for slaughter on landing unless a period of twenty-one days had elapsed between the time of call at the French port and their arrival at the English port, on the ground that infection from the cargo received in France but landed in America might be conveyed to the beasts subsequently received on the vessel in America and landed in England; and whether, as there was no restriction on the direct importation and distribution of merchandise from France into England, he would reconsider the regulations of the Board as regards vessels.—Mr. Walter Long replied that the landing of foreign animals had for very many years past been subject to the requirement that the vessel in which they were brought should not before taking them on board have touched within a specified period at a port in a country from which the importation of animals was entirely prohibited. This requirement was rendered necessary by the fact that some of the diseases against which this country legislated could be transmitted,

Digitized by Google

not only directly from animal to animal, but also through the medium of persons, substances, and things, and actual experience had shown that the danger was a very real one. He regretted, therefore, that he was unable to withdraw the requirement, and with regard to the particular period to be prescribed, he would say that some years ago it was reduced from twenty-eight to twenty-one days, and that he did not think it could be further reduced consistently with safety.

Poona Plague Administration.

Lord George Hamilton read to the House at this sitting a categorical reply by Lord Sandhurst, Governor of Bombay, to certain allegations with reference to the plague administration in Poona contained in a memorial addressed to the Bombay Government. This reply stated, among other things, that people were only sent to hospital after careful medical examination and if showing symptoms indicative of possible plague; that the greatest care was taken not to remove to the segregation camp any but those necessary to keep under observation, time being allowed for preparation and one person being allowed to stay behind to look after property; that Lord Sandhurst had not yet heard any allegations of indignity being substantiated; that native gentlemen were asked to accompany search parties, and did so to the very end; and that they were specially desired to bring to notice all complaints which reached them, and to mark down any offending soldier and report to officers that the search parties were instructed to have regard to religious feelings, and that the possibility of abuse of those feelings was minimised by the presence of the native gentlemen, and that Lord Sandhurst did not believe the possibility of indignity to native women owing to the presence of lady doctors and other ladies with the search parties.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Mr. Ballance: Surgery of the Nervous System.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in the last number of THE LANCET. It is intended, in future, to include the Index and Title page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

A NEW DEPARTURE AT AN INQUEST.

AN inquest was recently held at the Hove Town Hall relative to the death of a man named Jackson, who was found dead in a garden outhouse. There was nothing remarkable about the case, death being due to the rupture of an aneurysm of the first part of the aorta; but what we do think worthy of notice is that the medical man who gave evidence is reported as "having the heart produced and practically demonstrating to the jury the exact nature of the injury." We take it that this is a new departure and not one to be followed. Possibly in the future we may see the jury invited to attend the post-mortem examination and being duly edified by the medical man addressing them as follows:—"You will observe, gentlemen, that the deceased suffered from a new growth of the pancreas; the growth is carcinomatous in nature and has eroded the cœliac axis, thus giving rise to a sudden hæmorrhage, which proved fatal." From showing pathological specimens at an inquest to such a procedure as we have endeavoured to indicate above is but a short step, and we hope that the pathological demonstration will not be repeated.

Mr. S. Scott is recommended to make enquiry of the family practitioner.

AN ARTIFICIAL LARYNX.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers inform me who are the makers of an artificial larynx, with cardboard discs simulating diseases, for laryngoscopic practice, also an artificial fundus for ophthalmoscopy?

I am, Sirs, yours faithfully,

July 1st, 1897. MAGGIORE.

DR. STEELE'S JUBILEE ODE.

AT the request of some of our readers we append a literal translation of Dr. Steele's Jubilee Ode which appeared in THE LANCET of June 19th:—"From what source the British people derive their moral worth and the lustre of their empire, tell us, oh, Muse, who surveyest the world from the rising of the sun to his western decline, who hast skill to burst the barrier of time and to disclose the humble beginnings of our power, when the Silurians were bound with Roman fetters and their chief, Caractacus, before the tribunal of the Emperor Claudius, gave utterance to the prophecy: 'Not for ever will the haughty sway of the Romans endure; not for ever will Father Jove from his lofty shrine, or Mars the Avenger, provide for the City; four centuries will glide away and the Mistress of the World will collapse before the barbarians of the North. For Ulysses, having threaded the Pillars of Hercules on his last voyage to see the Islands of the Blest, was carried out of his course to the British strand, and there, having found a kindly host in the chief, after recruiting himself and his crew, he again put to sea, gratefully leaving behind him a forecast of the blessings in store for our Albion, which, he said, would one day be the mother of high-souled heroes, rich in a twofold empire, and continuing to subjugate lands and seas withheld from the Romans, until, lifted higher by their ruins, she would reign supreme—a QUEEN upheld by a purer faith, an EMPRESS formed to play a mightier part than Cæsar's." This prophecy, borne by the Ithacan king to the Britons, delivered by Caractacus to an all incredulous Rome, how tested it has been, how thoroughly fulfilled, let the world declare; let peace and civilisation, with their triumphs, declare, and freedom won for the people in harmony with law, and religion the boon-mother of salvation; let art declare, and the gifts dear to the Muses, as shown in the animation given to marble, in the eloquence given to painted canvas, in the inspiration given to the printed page; let the far-seeing statutes of a fatherly senate declare, and courts of justice equitable to the humblest of the accused, and the reverend order of the priesthood, loyal in its allegiance to the Cross. Nor, amid so many witnesses, let the confirmation of Æsculapius be withheld—Æsculapius, a soldier fighting a battle of his own and winning trophies denied to military leaders; Æsculapius, who, when charged with the interests of the State, strengthens its resisting power till epidemic disease and its agents drawn up for battle are put to the rout, giving back even before the trumpet sound; Æsculapius, who with the balm that by evaporation confers unconsciousness, lulls to sleep the patient, thus exempting him from dread of Machaon's inexorable knife and salutary severity; Æsculapius who, a nature-student, daring yet reverential, knows how to penetrate the sanctuary of life hitherto veiled from the uninitiated gaze; who knows in its intimate recesses, to surprise Disease, like the sleeping Proteus, who will presently reveal his strategy, the weapons he has mocked, the weapons he has come to fear; from which revelation there is derived for us a habit and rule of life ever more conducing to health and to the development of the race and the family alike, until we are renewed into a yet mightier generation and are carried up again into the Golden Age. Thrice propitious monarch, descended from so long a line of kings, VICTORIA! vouchsafed to the world, like a returned Astræa, and destined to be enrolled among the celestials; late be thy departure from thy foster-children! For, under thy providential sway ever more present, our good fortune will flow down in yet ampler volume, wafting us to that goal which is the aspiration of all pious natures, who, when once they have reached it, will behold Islands Blest in a truer sense that those beheld by the errant Hercules when he dared, across the Atlantic, to seize and carry off the golden fruit."

H. W. (Talgarth).—We agree that the information must have been sent to the paper by some one who knew, but it did not emanate necessarily from the person mentioned. Indiscreet friends generally make these communications.

"PELLAGRA?"

To the Editors of THE LANCET.

SIRS,—I venture to reply to "Vagamundo's" query from Crete in THE LANCET of July 3rd because I have had the opportunity of treating some 400 cases of pellagra in Cairo, and of studying the disease in Italy. The site of the eruption is suggestive of pellagra, but the "apertures filled with hard yellowish matter" are sufficient to negative that diagnosis. Pellagrous eruptions usually remind one of symmetrical trophic erythema, psoriasis, or ichthyosis, but pellagra should be diagnosed not only by its skin manifestations, but by diarrhœa, denuded epithelium of tongue, changes in patellar reflex, and tenderness of spinal nerves. The disease is not likely to be present in small children unless distributed among adult peasants in the island. Pellagra exists at Corfu and very probably also in Crete, for the peasants there live partly on maize.

I am, Sirs, yours truly,

Saville Club, W., July 7th, 1897. F. M. SANDWITH, M.D.

ECCENTRICITIES OF SUICIDE.

THE *Evening Standard* in a recent number had an interesting article under the above heading, appropriate to the time of year when, contrary to general opinion, the suicide curve rises. The selfishness of suicides is remarkable and is instanced by the case of a man who committed suicide in the classical way by opening his veins in a bath, a Turkish bath in this case. His thoughtless act ruined the proprietor, for the story got about and no one would use the baths afterwards. Perhaps the most eccentric method of attempted suicide was one which occurred in London not so very long ago. The would be self-murderer filled his mouth with gunpowder, so full that he could not shut it, and then inserted a lighted match. Instead, however, of his head being blown off, as he had hoped, the powder simply blazed out of his mouth, severely burning his lips, and having chosen the neighbourhood of a hospital for his experiment he was at once conveyed thither and treated with success. A somewhat similar instance happened a few years ago when a miner put a dynamite cartridge in his mouth, but in this instance his head was shattered to pieces.

Aphasia has omitted to supply us with his name and address. This proceeding is in keeping with the pseudonym which he has adopted, but we cannot respect his infirmity so far as to excuse the omission.

THE ADMINISTRATION OF CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—Would you kindly ask the profession for information in your widely read journal if any of them have experienced, seen, or heard of any ill effect having followed the use of inhaled pure chloroform, administered, on Snow's method, by means of the regulating inhaler? Over 1000 of these inhalers having been distributed over many different parts of the world, some of which may probably have been employed daily since 1889–1890, it would greatly enhance the value of the information if each correspondent would also give the number of cases in which the inhaler was employed and the amount of chloroform used on an average per minute.

We are, Sirs, yours faithfully,

July 6th, 1897. KROHNE AND SESEMANN.

F.R.C.S., M.R.C.P.—We have been unable to decipher our correspondent's signature.

THE TREATMENT OF URETHRAL STRICTURE BY ELECTROLYSIS.

WE have received a paper by Dr. Ramon Guiteras, Professor of Anatomy and Operative Surgery at the Post-graduate Hospital of New York, upon the subject of the electrolysis of urethral strictures. There is, of course, nothing new in the main treatment, for electrolysis for this condition was practised so far back as 1839 by Crussell, more systematically by Mallez and Tripier in 1867, and comparatively recently by Steavenson and Bruce Clarke in 1886. One new point about Dr. Guiteras' method is, however, the use of an electrode modelled on a Maisonneuve urethrotome, the knife being made of platinum and blunt, so that in use the instrument passes through the stricture before the current is turned on. This method, of course, implies that the stricture is not impassable, and in cases where the obstruction is impassable we do not see that Dr. Guiteras' method has any advantages over the common electrode used by Steavenson and Bruce Clarke.

Practice in Jersey.—According to the definitions given in the Medical Act, 1886, "the expression British possessions means any part of Her Majesty's dominions exclusive of the United Kingdom, but inclusive of the Isle of Man and the Channel Islands."

During the week marked copies of the following newspapers have been received:—*Blackburn Standard, Le Temps (Paris), Hull News, Birmingham Gazette, Baillie, Dover Express, Newcastle Leader, Harrogate Advertiser, Sheffield Independent, Oxford Journal, Southport Visitor, Accrington Observer, Barnsby Chronicle, Liverpool Daily Post, Alnwick Guardian, Times of India, Pioneer Mail, Oban Times, Architect, Goole Times, Yarmouth Advertiser, Folkestone Chronicle, Carnarvon Herald, Salisbury Journal, Bedford Standard, Builder, Wolverhampton Chronicle, Yorkshire Post, Western Morning News, Dundee Courier, Observer and Chronicle (Bournemouth), Hastings Times, Leeds Mercury, Stroud News, Doncaster Chronicle, Woking Mail, Essex County Chronicle, Manchester Courier, Maryport News, Halifax Guardian, Bristol Mercury, Worcestershire Chronicle, Rugby Advertiser, Southampton Observer, Midland Free Press, Leicester Post, Sussex Daily News, Cambrian, Devon Weekly Times, Kent Messenger, Chatham News, Carlisle Journal, Hampshire Telegraph, Tyrone Constitution, Brighton Gazette, Weekly Free Press and Aberdeen Herald, Mining Journal, Hertfordshire Mercury, City Press, Christian World, Reading Mercury, Local Government Chronicle, Blackburn Times, Daily Express (Dublin), Bradford Observer, Surrey Advertiser, Local Government Journal, Norfolk West Standard, Norwood Weekly Herald, Cape Times, West Middlesex Herald, Weekly Times and Echo, Forfar Herald, Devizes and Wiltshire Gazette, &c., &c.*

ABSTRACT OF

The Cavendish Lecture

ON

OVARIAN TUMOUR WITH PREGNANCY.

Delivered before the West London Medico-Chirurgical Society on July 2nd, 1897,

BY SIR JOHN WILLIAMS, BART., M.D., F R C.P. LOND.,

PHYSICIAN-ACCOUCHEUR TO H.R.H. THE DUCHESS OF YORK; CONSULTING PHYSICIAN FOR DISEASES OF WOMEN, UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—The subject which I have chosen for the Cavendish Lecture this year is the complication, Ovarian Tumour with Pregnancy. Although the condition is not one of great frequency, yet it is not one of very uncommon occurrence, while, by reason of the large mortality resulting from it, the importance which must be attributed to it is great. I have collected 375 cases of the complication, with 461 preghancies, several of the patients having been pregnant more than once.

The first question which demands our consideration is: Is pregnancy a cause of ovarian tumours? Does gestation originate such growths in the ovary? I say that this is the first question, because it has been asserted that pregnancy frequently gives rise to these new growths. To prove this statement—that pregnancy is the cause of ovarian tumour in any given case—is, in the present state of our knowledge of the causes of tumour, not possible; but if we put the question in the following form—Does ovarian tumour occur with greater frequency in women who are or have been pregnant than it does in women who are not and have never been pregnant?—I think that I shall be able to produce evidence which will enable us to find a definite answer, and that in the negative. I have taken a series of cases of ovarian tumour in which the patients are divided into the married and the single, and I shall regard the married as mothers and the single as not mothers. This assumption may not be quite accurate, while it is the nearest approach to accuracy that I have been able to obtain. Moreover, the error in it is not so large as would at first sight appear, for the error made by regarding all married women as mothers is balanced by that made by regarding all unmarried women as not mothers.

If, then, we take the 1000 cases of ovarian tumour operated upon by Spencer Wells and divide them into groups corresponding to the age groups into which the Registrar-General divides the married and the single in the population generally, we obtain the following figures. There were in Spencer Wells's 1000 cases—

	Married.	Single.
Between the ages of 20 and 25 years	23	80
,, ,, 25 ,, 35 ,, ...	133	138
,, ,, 35 ,, 45 ,, ...	154	78
,, ,, 45 ,, 55 ,, ...	168	65
,, ,, 55 ,, 65 ,, ...	74	27
Aged 65 ,, upwards	7	6

From these it is seen that between the ages of twenty and twenty-five years ovarian tumour occurs in the single rather more than three times as frequently as it occurs in the married; while between the ages of twenty-five and thirty-five it occurs with almost equal frequency in the two classes. After thirty-five years of age the proportion is reversed, and the disease is met with twice as frequently in the married as it is in the single; between forty-five and fifty-five two and a half times as often; between fifty-five and sixty-five nearly three times as often; but in those above sixty-five years of age it is found in each class with almost equal frequency. Looking at these figures alone it would appear that pregnancy is a potent factor in the causation of ovarian tumours; for from thirty-five to sixty-five years of age, when marriage may be considered to have exercised its full effects, the married contribute a far greater number of ovarian tumours than do the single. Such a conclusion is, however, quite erroneous. This apparent result of marriage arises from the change which takes place in the social condition of the population and the consequent alteration in the number of the married and the single—the number of the married undergoing rapid increase at the expense of the single. To correct the error conveyed by the figures I have given we must take into account the proportion of the number of the married to the single in the population generally at the different periods of life under which they have been grouped.

Turning to the Registrar-General's Report for 1891 I find the proportion of the married to the single women to be:—

	Married.	Single.
Between the ages of 20 and 25 years	30	70
,, ,, 25 ,, 35 ,, ...	67	33
,, ,, 35 ,, 45 ,, ...	83	16
,, ,, 45 ,, 55 ,, ...	87	12
,, ,, 55 ,, 65 ,, ...	89	11
Aged 65 ,, upwards	89	11

By comparing these figures with those derived from the 1000 cases operated upon by Spencer Wells we shall have a more correct idea of the proportional frequency of ovarian tumours at the several periods of life under which they are grouped.

Now in the series of Spencer Wells we find between the ages of twenty and twenty-five years 23 married and 80 single women, or a proportion of rather more than 1 married to 4 single, while, according to the Registrar-General, the proportion of married to single women in the total population at this period of life is from 30 to 70, or 1 to 2·33; that is, speaking in proportion, 1 married woman produces one ovarian tumour, while 2·33 single women produce four, or 3 married women grow three tumours, while 7 single women grow twelve. Did ovarian tumours occur with equal frequency in the married and in the single between the ages of twenty and twenty-five years, the number in Spencer Wells's series would not be 23 married and 80 single, but 34 married and 80 single.

In the next group—between the ages of twenty-five and thirty-five years—this difference in the comparative freedom from ovarian tumour in favour of married women becomes still more marked, for in this group, in the series of Spencer Wells, I find 133 married and 138 single women. According to the Registrar-General's report the total number of married to the total number of single women in the population is as 67 to 33—that is, the married are twice as many as the single, and yet the single women furnish rather more ovarian tumours than the married. This disproportion is still more emphasised in the two next groups.

Between the ages of thirty-five and forty-five years there were 154 married and 78 single women the subjects of ovarian tumour. Here the number of the married is just twice that of the single. But what is the proportion between the number of the married and of the single in the general population? The Registrar-General states that they are as 87 to 12, or more than seven times as many, and yet, instead of producing seven times as many tumours, the married only furnish us with twice as many as the single.

Between the ages of forty-five and fifty-five years in the series of Spencer Wells, the number of the married is 168 and of the unmarried 65, while in the general population at this period of life the married are to the unmarried as 89 to 11, or eight times as many, and yet they show only two and a half as many ovarian tumours. The same remarks apply literally to the next group, while the difference in favour of the married is still more marked in women of sixty-five years and upwards.

Between the ages of fifty-five and sixty-five years there were 74 married and 27 single women operated upon by Spencer Wells, while the proportion of the married to the single in the general population is eight to one; yet the single present nearly a third as many ovarian tumours as the married, or nearly three times their proper share, were both classes subject equally to ovarian tumours. At sixty-five years and upwards there were 7 married and 6 single women in Spencer Wells's series, while in the general population there are eight married for every unmarried woman. At this period of life, then, a number of single women furnish eight ovarian tumours for every single tumour presented by the same number of married women.

I now turn to another aspect of the question. If pregnancy, as has been maintained, is a cause, and a frequent cause, of ovarian tumour, it may fairly be expected that with each successive pregnancy the liability to ovarian tumour would increase. I find, however, among the cases of ovarian tumour with pregnancy which I have collected, in the first place, that of the 228 cases in which the number of the pregnancy is noted 87, or more than one-third of the total

Digitized by Google

were primiparæ. Again, not only do primiparæ form so large a proportion of the total number of cases, but ovarian tumour with pregnancy does not only not occur with greater frequency, but it becomes on the whole rarer with each successive pregnancy, for among the cases there are—

In the second pregnancy	... ...	30	instances only.
,, third ,,	... ...	21	,, ,,
,, fourth ,,	... ...	14	,, ,,
,, fifth ,,	... ...	15	,, ,,
,, sixth ,,	... ...	9	,, ,,
,, seventh ,,	... ...	11	,, ,,
,, eighth ,,	... ...	4	,, ,,
,, ninth ,,	... ...	7	,, ,,
,, tenth ,,	... ...	1	,, ,,
,, eleventh ,,	... ...	2	,, ,,
,, twelfth, fifteenth, and nineteenth each		1	,, ,,
and other multiparæ	... ...	26	,, ,,

This shows almost a steady diminution of ovarian tumour with each successive pregnancy, the reverse of what we should expect were gestation a cause of ovarian growth.

These facts—namely, (1) that the proportion of cases of ovarian tumour in the married to the number of married women in the population is far smaller than the proportion of cases of ovarian tumour in single women to the number of single women in the population or, in other words, that ovarian tumour is proportionately far less frequent in the married than in the single; (2) that a large number of the cases of ovarian tumour with pregnancy occur in primiparæ, and that 25 of the cases were known to be the subjects of the tumour before conception had occurred, and that 57 were subjects of dermoid cysts, thus making a total of 82 in which the tumours were present before gestation commenced; and (3) that ovarian tumour with pregnancy is met with on the whole with less frequency in each successive pregnancy appears to show that pregnancy is not a factor in the causation of these growths.

The next question that demands our notice is, Does pregnancy occurring in the subject of an ovarian tumour favour the growth of the tumour? This must be considered under two separate heads—(1) Does the process of gestation itself give an impulse to the growth of the tumour; and (2) Does the tumour grow more rapidly after labour and during the lying-in period?

[Sir John Williams here discussed the first of these questions at considerable length. His conclusions were as follows:]

There is no uniformity in the conduct of the tumour in different cases. The whole of this evidence and the small number of the cases in which the growth of the tumour was rapid appear to show that pregnancy exercises no influence in accelerating the growth of ovarian tumours. The second part of the question relating to the growth of ovarian tumours in connexion with pregnancy is, What is the effect of delivery and lying-in upon it? Is it to accelerate it? It has been held that delivery, by diminishing the intra-abdominal pressure, relaxing the tension of the abdominal walls, and removing pressure from the tumour gives rise to rapid increase in it. I will not discuss this theory, but simply state that I attach no weight to it, and proceed to lay before you the facts which I have collected bearing on the question, and which to my mind furnish the answer to it. After 69 deliveries the tumour appears not to have grown, and after 32 it increased in size. In one of the 32 cases a sudden increase took place on the fourth day; in another a like increase occurred on the ninth day; 9 of the cases are said to have increased slightly, slowly, or gradually (1 during an attack of peritonitis, and 1 suppurated); 11 increased rapidly, 3 of them with peritonitis, or while undergoing suppuration. The sudden increase in 2 cases, the one on the fourth and the other on the ninth day, is probably due to twisting of the pedicle or hæmorrhage into the cyst, while peritonitis or suppuration was probably the cause in 3 cases. This leaves 8 cases in which there was rapid growth of the tumour after delivery, and 69 in which there was no appreciable growth, and 19 in which there was no unusual growth; that is, a total of 88 cases in which there was no unusual increase, and of 8 in which the tumour grew rapidly. These figures seem to show that the influence of delivery and the puerperal processes is not to accelerate the growth of ovarian tumours. There are some observations in the notes which are interesting in this connexion, because they refer to another kind of change in the ovarian tumour after delivery—a diminution in size instead of an increase. In one case observed by Dr. Milne the patient had three children, and the tumour is said to have diminished in size after each pregnancy. In one case the cyst ruptured during labour, and no trace of it could be found during a subsequent labour. In another the cyst burst some time after the puerperal period, and the abdomen was tapped. No trace of the cyst could be found at the following labour. In another the tumour disappeared, and the patient had two children afterwards. In another the tumour disappeared and could not be found in a subsequent pregnancy. In another the tumour was tapped twice and drained after the second tapping; the cyst suppurated, but gave no further trouble. The patient had living children subsequently. In another the cyst suppurated and discharged pus and hair, and gave no trouble at the next confinement; and in a case recorded by Dr. Robert Lee the tumour decreased considerably in size after delivery, and the administration of liquor potassæ. Of the eight cases the tumour is said to have decreased in size after delivery in two, to have disappeared with or without rupture in four, and to have given no trouble after having undergone suppuration in two. The cysts which disappeared not to refill after rupture may have been, and probably were, cysts of the broad ligament.

I pass on now to consider very shortly the question of the relation of pregnancy to malignant disease of the ovary. Leopold has made the extraordinary and startling suggestion that pregnancy is a cause of cancer of the ovary; and Wernich holds that pregnancy occasions malignant degeneration of ovarian cysts. Leopold bases his suggestion upon two cases—one published by Spiegelberg and one observed by himself. Spiegelberg's case is briefly as follows. The patient, who was thirty-six years old, was pregnant for the second time; she was delivered of twins on March 20; one was dead at birth and the other died in the course of a few hours. The tumour was discovered after the delivery. On March 30 the patient died uræmic, with peritonitis, the result of hæmorrhage into the cyst and rupture of it. Both ovaries were changed into masses of myxo-sarcoma carcinomatosum, no trace of ovarian tissue remaining. Leopold's case regards a patient, thirty-six years of age, pregnant for the third time. She bore her second child in her thirty-fourth year, after which she menstruated regularly until her thirty-fifth year, when menstruation ceased, and in December, 1863, she gave birth to a six months' fœtus. After her delivery the medical man discovered an abdominal tumour, the nature of which was not clear. Puncture proved it not cystic. She died about two months after her confinement. Each ovary was of the size of a man's head and a mass of medullary cancer.

These two cases form a very slight foundation for the theory that pregnancy is a cause of cancer of the ovary. Even if it were known that both ovaries had become the seat of disease in the course of pregnancy, Leopold's theory would be almost like a pyramid standing on its apex. But even this meagre knowledge is not forthcoming, for in both cases the tumour was not discovered until after delivery, and the state of the organs at the time of conception is not known, and the inference that the disease began in the course of, and was caused by, pregnancy is a pure assumption. Indeed, the only conclusion which can be drawn from these two cases is that the ovaries were not entirely cancerous at the time of conception, that a portion of the ovarian tissue was healthy and capable of discharging an ovum.

Wernich's view that pregnancy gives rise to malignant degeneration in previously benign growths is based upon an equally slender foundation—namely, two cases—one observed by himself and one by Kursteiner. The original report of Kursteiner's case I have been unable to obtain, and the extracts given from it by Wernich are of too meagre a character to be of any value. Wernich's case was a woman, twenty years of age, who had suffered from pleurisy for a long time, and was known to have a tumour in the abdomen, the nature and point of origin of which were doubtful. Whether there was any relation between the tumour and the pleurisy is not stated. The tumour, however, gave the woman no trouble, and remained indolent for one year. She conceived and miscarried at the eighth month. Shortly before the miscarriage she complained of violent pain in the tumour. She rapidly lost flesh, and died three weeks after her delivery. No marked growth of the tumour was observed during pregnancy or after delivery. Labour was not hindered by it. At the necropsy the right ovary was found to be a mass of medullary cancer, breaking down in places. No trace of the original structure of the ovary was discovered,

Digitized by Google

but in the tumour was found a small cyst having glairy contents with papillary growths on its inner surface. The remarks made respecting Leopold's view and the reasons for them are applicable to Wernich's; but, further, in considering Wernich's view it should be remembered (1) that cancer is occasionally found in cystic tumours of the ovary; and (2) that after the removal of cysts which appear to be of a benign character malignant disease sometimes develops in the stump of the pedicle, and in these two well-known facts are to be found, I think, the explanation of Wernich's case, and not in what I must characterise as a far-fetched theory of a malignant influence exercised by pregnancy. Moreover, cancer of the ovary, apart from pregnancy, is not very uncommon, but I have no means of judging of its frequency except by my own experience, and if I may judge by that, cancer of the ovary with pregnancy does not appear to be proportionally more frequent than cancer of the organs apart from that condition.

[Having shown that pregnancy does not originate ovarian tumours, benign or malignant, that it does not accelerate their growth, and that it does not cause malignant degeneration of benign tumours, Sir John Williams proceeded to describe the effects of gestation, delivery, and the puerperal processes upon these growths, the effects being twisting of the pedicle, rupture and laceration of the tumour and their consequences, hæmorrhage into the cyst, and suppuration. He stated that twisting of the pedicle was said to have occurred in twenty-one instances among the cases collected, or about 6 per cent. In the 375 cases of ovarian tumour with pregnancy he found that rupture of the ovarian cyst occurred 13 times, or 3·5 per cent., during gestation. During labour and after parturition it happened 25 times, or in nearly 10 per cent. of the cases and 8 per cent. of the pregnancies. He continued:]

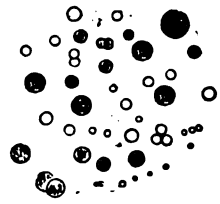
I have now finished what I have to say respecting the influence of pregnancy upon ovarian tumours, and I have yet to consider the influence of the tumour upon pregnancy, labour, and lying-in. We find that abortion or premature labour occurred spontaneously in 58 out of 461 pregnancies. In 24 of the cases the tumour was cystic and in 5 dermoid, the total of cystic tumours being 221, and of dermoid 71, so that abortion appears to be somewhat more frequent with cystic than with dermoid tumours. Abortion or premature labour occurred in 8 out of 14 cases of cancer, and was induced in 1, while nothing is stated upon the point in 5, so that cancer appears to have a baneful influence on gestation The part played by ovarian tumours in labour depends firstly and largely upon the situation of the tumour, and, secondly, and in a less degree, on its size. When the tumour is placed in the pelvis, even when of comparatively small size, it impedes the passage of the child; on the other hand, if it be situated in the abdomen, it depends mainly upon its size whether it does or does not interfere with the progress of labour. Among the cases I have collected there are 178 (or about 2 out of 5) in which the labour was more or less natural—that is, delivery was effected without artificial help. To realise the difficulties caused by these tumours during delivery we must look to the cases which required artificial help, and to the examination of these I now turn. The means which have been employed to overcome these difficulties are reposition, or raising the tumour from the pelvic into the abdominal cavity, so as to place it out of the way of the descending head. In many cases this could not be accomplished, then tapping was resorted to, forceps, version, craniotomy, and Cæsarean section, or ovariotomy, as circumstances dictated.

[Sir John Williams here gave statistical details of the results of these various procedures. He continued:]

The mortality consequent upon ovarian tumour complicating pregnancy is very great, and is only equalled in midwifery by that occurring in severe outbreaks of puerperal fever.

The mortality after tapping is	...	...	26 per cent.[1]
,, ,, ,, forceps is	...	...	29 ,, ,,
,, ,, ,, version is	...	...	33 ,, ,,
,, ,, ,, craniotomy is	...	...	44 ,, ,,
,, ,, ,, abortion and premature labour is	...	...	17 ,, ,,
,, ,, ,, Cæsarean section is	...	...	90 ,, ,,
,, ,, ,, ovariotomy is	...	...	10 ,, ,,

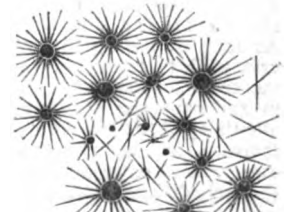
The great mass of this mortality take place after delivery. Comparatively few cases die during pregnancy when not interfered with. It is clear from the record of deaths that little can be done to diminish the danger by the usual obstetric operations, and it seems to me that our efforts should be directed to the prevention of injury to the ovarian growth and the parts adjacent to it, abdominal and pelvic. At present I see but two ways in which this can be accomplished. One is the removal of the tumour during pregnancy or labour, and the other is the anticipation of labour by the Cæsarean section. Small tumours situated in the abdomen, or tumours situated in the pelvis, which can be raised up into and retained in the abdomen do not appear to suffer much injury during labour, but with this exception I think that all cases should be operated upon. I should have recourse to Cæsarean section only in cases in which the removal of the tumour is found to be impossible, be it from adhesions deep down in the pelvis to the uterus or for other cause. On the other hand, ovariotomy during pregnancy is a tried operation, and it has proved as successful during pregnancy as apart from pregnancy, and it gives a mortality of less than half that from natural labour with ovarian tumour; and no other method of treatment has as yet given, nor does any promise, such good results.



[1] In a large number of the cases operated upon more than one operation was resorted to, such as tapping, forceps, craniotomy, and the same cases appear therefore under each of the operations.

ON THE PATHOGENESIS OF GOUT.[1]

BY DR. C. MORDHORST.



BEFORE proceeding to my actual theme I will refer in a few words to the results of a considerable number of experiments and observations under the microscope, which will shortly be published in the *Zeitschrift für Klinische Medicin*. Whenever uric acid is added to an alkaline fluid the base of the latter combines with the former, producing a uric acid salt (urate). When the solution is over-saturated with the salt it becomes in the first instance precipitated in the form of small globules, which run together and form larger globular masses. On first forming, these globules are so minute that they are invisible even with the highest powers of the microscope. As the drop of fluid on the slide begins to evaporate they soon begin to appear in the microscopic field as barely visible specks. They may attain a variety of sizes and even become fifty, or more, times as large as leucocytes. They may with advantage be called globular urates (Kugelurate). The term "amorphous" is incorrect, as they are invariably distinctly globular in shape (Fig. 1). The quantitative composition of these globular

FIG. 1.

Globular urates, consisting of sodium urate, a 0·6 per cent. solution of soda not saturated with uric acid, evaporated to half its bulk. The large globules were of a pale yellow. The more uric acid these urates contain the darker they become in colour. Enlarged 140 times.

FIG. 2.

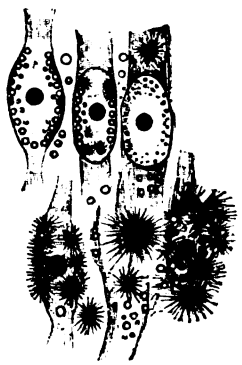
Needle urates composed of biurate (acid sodium urate). The sediment from a 1 per cent. solution of soda supersaturated with uric acid, after twenty-four hours. Enlarged 140 times.

urates is very variable. The greater the excess of alkalies, say, sodium, the solution contains, the more base and the less acid enters into the composition of the salt. Properly speaking, a crystalline salt, consisting of two molecules of sodium and one molecule of uric acid, the so-called neutral sodium urate, does not exist. This combination, as well as all others which contain more sodium than uric acid, does not form crystalline salts, but globules, or globular urates, and possesses the property of being decomposed sooner[2] or later

[1] A paper read at the Medical Congress at Wiesbaden in 1896.

[2] I have used the term acid urate of sodium throughout this translation, although the common term is biurate.

Digitized by Google



into acid urate of sodium and sodium. In order to have a short term for these urates I have called them "needle urates." The time necessary for the crystallisation of the "globular" forms is longer the more sodium they contain (Fig. 2).

The sole cause for the precipitation of globular urates is the super-saturation of a solution already containing them. Such a super-saturation of a solution saturated with uric acid occurs: (*a*) on adding more uric acid; (*b*) on evaporating some of the water in the solution, either by exposure to air or by boiling, or by the addition of some colloid substance (albumin, starch, or gum), which absorbs some of the water as it dissolves; (*c*) on cooling the solution when it has become saturated, or nearly saturated, with globular urates at a higher temperature, since a warm super-saturated solution can hold more globular urates in complete solution than a cold solution; and (*d*) on diminishing the alkalinity of the solution by the addition of acids or acid, neutral or faintly alkaline salts. This is partly due to their taking up some of the water as they dissolve, as was the case with colloids. The solubility of globular urates is directly proportional to the amount of sodium they contain. The globular urates are always a first stage in the formation of needle urates, and on these latter dissolving the former are a transition stage. The largest amounts of uric acid and needle urates are dissolved in a solution containing between 0·4 and 0·7 per cent. sodium carbonate, sodium bicarbonate, or bisodium phosphate. In the fluids of the body uric acid circulates as a urate in the invisible globular form. After these preliminary remarks I pass on to the more intricate processes leading to the deposition of uric acid.

To begin with, I would remark that sodium urate is only deposited in those organs and tissues which are sparingly or not at all supplied with blood-vessels, and the nutrition of which accordingly takes place only or principally by means of lymphatic vessels or lymph spaces. The connective tissue of muscles, fasciæ, tendons, tendon sheaths, nerve sheaths, ligaments, cartilage, perichondrium, or periosteum are almost exclusively the seat of gouty affections. There must of course be some reason for this. I have already on a previous occasion made the suggestion that the difference in reaction of the fluids of these tissues and of the blood is the only cause producing these results. My recent and numerous experiments have confirmed this belief. Maly has proved that acids filter more rapidly through animal membranes than do alkalies and alkaline salts. That the former diffuse more rapidly than the latter was shown by Hoffmann, Runeberg, Chahrié. Cartilage and connective tissue cells, which lie far removed from blood capillaries, are nourished by processes of filtration, diffusion, and osmosis. This mode of nutrition, however, must of necessity lead to a lessened alkalinity both of the above-mentioned cells and of their intercellular substance. As long as the alkalinity of the blood and the quantity of uric acid in it remain normal there is, even under circumstances otherwise unfavourable, no deposition of sodium urate in the cartilage and connective tissue. But should the alkalinity of the blood diminish and the amount of uric acid increase—as, according to the results of older as well as more recent experiments (Klemperer), is the case in gout—then conditions exist under which a deposition of urates in cartilage and connective tissue can occur. In my opinion the actual process is as follows.

The organ or tissue in question has been rendered very rich in fluids by previous functional activity. Any blood-vessels in the tissue itself or in the immediate neighbourhood are strongly dilated. The lymphatics of the tendons and fasciæ of the muscles, which possess numerous stomata, are likewise distended far beyond their normal state—viz., at rest. The interchange of fluids between the connective tissue cells and the intercellular spaces on the one hand, and the lymph spaces of the tissues and the lymphatic vessels on the other hand, is excessively active, and the difference in their reaction is very slight accordingly. Now if there should be a sudden cessation of this activity in the tissues, and if they are suddenly cooled down by the influence of external cold, then a rapid change takes place in their nutrition. Owing to the irritation due to cold the tissues contract and the blood-vessels and lymphatics do the same. The interchange of fluids is reduced to a minimum; the processes of filtration, diffusion, and osmosis are much slower; the alkalinity of the protoplasm of the cells, of the intercellular substance, and of the synovia of the joints and tendon sheaths decreases. The cooling of the fluids, their loss of water, and their diminished alkalinity all combine to produce a super-saturation with globular urates, and therefore a precipitation of the latter, both in the connective tissue cells themselves, in the intercellular and lymph spaces, and in the synovial fluids. This occurs all the more readily, as, owing to the cooling of the tissue, which up till now had been very full of fluids, the water or less concentrated fluid is forced most rapidly through the cell membranes. The protoplasm of the cells as well as of the intercellular substance contains sodium urate in such quantities that the combined action of the above-mentioned factors leads to their precipitation, first, in the small globular form, possibly even invisible under the microscope. In the cells these accumulate near the cell membrane and enlarge by fusion. But even in the intercellular substance the globular urates accumulate on the outer surface of the cell membranes, or, if the precipitation is copious, are forced towards the lymph spaces. Here they may accumulate to such a degree as to block not only the exits of the lymph spaces, but even the lymphatic vessels, and this, if continuing for some time, may cause obstructive œdema, inadequate nutrition of the tissue with consequent degeneration (Ebstein's necrosis), and finally pain. The subjoined semi-diagrammatic figures are intended to demonstrate this process (Figs. 3, 4, 5, and 6). Now as long as

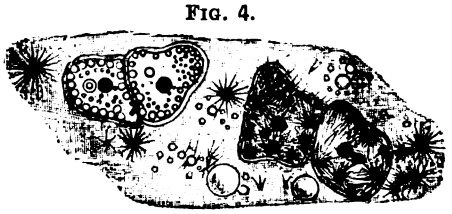


FIG. 3.

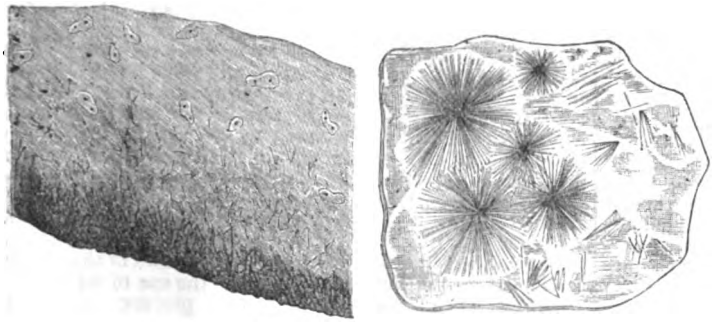
Fibro-cartilage. The cells are partly filled with very small globular urates, which in the two lower cells have thrown out needles of biurate (acid sodium urate) in all directions. In the intercellular substance between the longitudinal fibres both globular and needle urates are seen. Early stage; at a later stage the globules completely disappear.

the globular urates retain their forms we have, in my opinion, to deal with "rheumatism," that well-known complaint from which every elderly person probably at some time or other suffers. If within from half an hour to a few hours this "rheumatism," which has arisen from a sudden chilling of the tissues attacked, is properly and efficiently treated—namely, by massage, hot applications, &c.—it will disappear just as rapidly as it appeared. With the

FIG. 4.

Articular cartilage with globular and needle urates in the cells and intercellular substance.

rapidly increased supply of blood to the tissue, warmth, water, and alkaline salts are brought to it. The combined action of these three factors is a solution of the globular urates, which, added to the more rapid circulation of the fluids, in a short time bring the tissue to a normal state.



Should the "rheumatism," however, not be treated so rapidly or efficiently, or should the tissue be frequently exposed to such chills, then the globular urates are not completely re-dissolved—a certain amount remains behind in the tissues and produces symptoms of pain on pressure or movement. In those cases of so-called "chronic articular

Digitized by Google

rheumatism," where no deposit of acid sodium urate can be demonstrated microscopically after death, the precipitated urates have retained their globular form and have not been recognised as such. Scrapings of the tissues of parts thus affected would no doubt prove the presence of urates far more often if the murexide test were always employed.[3]

Now, why is it that these globular urates do not change into needle urates? In the course of my introductory remarks I referred to the fact that globular urates are converted into needle urates more slowly in proportion as there is more sodium and less uric acid in their composition. My experiments show that even when very poor in acid and very rich in sodium these globular urates may ultimately change into needle urates, often after six or eight weeks, provided they remain in their original fluid. This is not always the

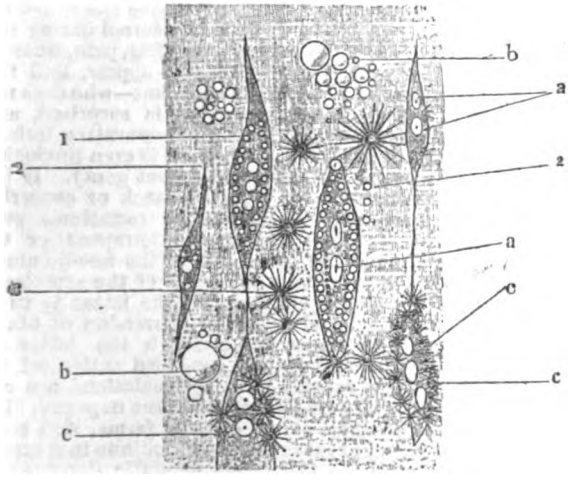


FIG. 5.

Articular cartilage after Garrod, enlarged 220 times. The globular urates have become completely converted into needle urates and stellate groups of needle urates.

case, however, and I only mention the fact without attempting to give any explanation for it. In the living organism the conditions are very different from those existing during experiments outside the body. I take it that in the former, solution and re-formation of globular urates go on side by side, and the globular urates often have no time to change

FIG. 6.

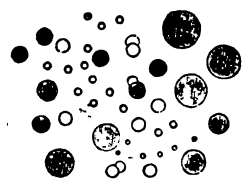
Connective tissue showing deposition of needle urates and globular urates in the cells and intercellular substance. 1, Connective tissue cells with nuclei (a). 2, Intercellular substance; (b) Globular urates; (c) needle urates and stars of needle urates.

into needle crystals. The blood of persons suffering from "chronic rheumatism" is less alkaline than that of a healthy person, as shown by Lepine, but yet is more alkaline than that of a person suffering from well-marked gout. The alkalinity of the blood varies, not only with each individual, but even in the individual it varies according to the time of day; this latter variation is, however, confined within definite limits. Klemperer has quite recently proved that in gouty individuals the alkalinity of the blood is considerably below the normal standard, but here also we find variations. If only slightly below normal we are dealing with gouty patients suffering from so-called "chronic rheumatism." Klemperer's investigations have proved that the quantity of uric acid in the fluids of the body is inversely proportional to the amount of alkaline carbonate they contain. This result is in perfect accord with the results of numerous experiments by F. Walter, F. Chvostek, Kleine, Hartnack, and others, according to whom the protoplasm owes its capacity for taking up oxygen entirely to the presence of alkaline carbonates in its composition.

The more alkaline carbonates a tissue contains the greater is its capacity for taking up and utilising oxygen, and the more active therefore is the oxidation of uric acid. In persons in whom the alkalinity of the blood is only slightly below normal the quantity of uric acid present is only slightly above normal; the globular urates therefore contain relatively little acid in their composition, and so retain their globular form for a long time. Where the alkalinity of the fluids is less, and the quantity of uric acid in the blood greater, the precipitated globular urates contain more uric acid and less sodium, they give up some of this sodium to the surrounding fluids, and themselves become converted into needle urates of acid sodium urate. These are the only deposits of urates which are considered characteristic of gout by most authorities. I am convinced that "chronic gout" arises in the following way. The earliest stage is not distinguishable from chronic rheumatism; the accidental and exciting causes are identical. Whereas, however, in the latter the globular urates contain relatively little uric acid, in gout they contain a large amount. My experience is that globular urates which are rich in uric acid often become converted into needle urates and stars of needle urates within from half an hour to twenty-four hours and even less. Now in chronic gout a similar conversion of globular urates takes place, although under certain circumstances a considerable interval of time may elapse before the process is completed. When completed the acute and spontaneous pains diminish, and the uratic deposits only prove their presence by tenderness felt on pressure or movement. The signs of inflammation, pain, redness, and œdema owe their appearance to the accumulation of, and blocking by, the globular urates in the cells, intercellular substance, lymph lacunæ, and lymphatics. Just as globular urates are a first stage in the development of needle urates, so also the deposition of the former precedes the deposition of the latter; in other words, "rheumatism" often precedes chronic gout.

Let us now investigate more in detail the transformation of globular urates into needle urates and its consequences. I have already mentioned that globular urates tend to be pushed towards the cell membrane of the cells in the cartilage and connective tissue, and here accumulate in number and enlarge in size by fusion. Sooner or later they commence to throw out needles at their periphery, and ultimately form stars of needle urates; these latter pierce the protoplasm and cell membrane, which is also pierced by the needles on its outer surface. The cell membrane and cell become completely destroyed, and in this way necrosis of the tissue commences. As this process of needle formation extends, so the necrosis increases. In this case, therefore, the deposition of globular urates is the primary event and the necrosis is secondary. Von Noorden's "ferments" and Klemperer's "gichtstoff," are accordingly nothing more than globular urates, originally minute, but which have enlarged rapidly, have formed needles in all directions, and so killed the tissues.

It still remains for me to discuss the origin of an acute attack of gout. Before giving my views on this subject I would beg you to picture to your mind the appearances seen under the microscope when a drop of dilute acid is added to some solution of soda saturated with uric acid, which drop has been placed on an uncovered slide. In the centre, which gives an acid reaction, a turbidity soon appears, from which uric acid crystals will have developed in a few minutes. The outer zone gives an alkaline reaction and



[3] Levison (Copenhagen) examined the metatarso-phalangeal joints of one or both feet, and in some cases other joints also, in forty post-mortem examinations. In twelve cases he was able to prove the presence of uratic deposits by means of the murexide test, although only a few joints were examined.

Digitized by Google

contains larger or smaller globular urates. The intermediate zone, giving a neutral or faintly acid reaction, presents long and well-formed crystals often fifty times, or more, larger than white corpuscles. The process in an acute attack of gout I represent to myself as follows: Owing to some incidental circumstance—e.g., a good dinner accompanied by considerable indulgence in wine or beer, or some digestive disturbance—the alkalinity of the blood becomes greatly diminished. Owing to filtration, diffusion, and osmosis the already greatly reduced alkalinity of the tissue fluids becomes further diminished, the fluids are no longer capable of holding the globular urates in solution, and these are accordingly precipitated as minute globules, resembling urates deposited in urine, and their accumulation in large quantities gives rise to those prodromal symptoms so often preceding an acute attack of gout. If the alkalinity of the blood is still further decreased, so that the fluids of the body become either neutral or even faintly acid, then the large crystals above mentioned form and block up the lymphatics of the neighbourhood more or less completely, even if the vessels are of large calibre. The mechanical irritation and the lymphatic obstruction thus produced give rise to severe inflammatory symptoms, œdema, &c. The attack will continue so long as the acidity of the fluids lasts. On renewed increased alkalinity the inflammatory symptoms subside, because the crystals have been again converted into globular urates. Should the alkalinity increase still further the globules become dissolved and the attack has passed off, leaving no sequelæ. If, on the other hand, the alkalinity still remains at a low level the globular urates will persist as such for some time, and finally become converted into needle urates. In this case uratic deposits have formed in the affected tissues. This theory, therefore, also explains the fact that in some cases an acute attack of gout leaves no deposits, whilst in other cases distinct deposits are left.

I still have to mention a phenomenon which until now has never been satisfactorily explained—the exacerbation of gouty symptoms so frequently observed during a course of treatment by baths and the waters here in Wiesbaden. This is a fact so generally recognised that there can be no doubt

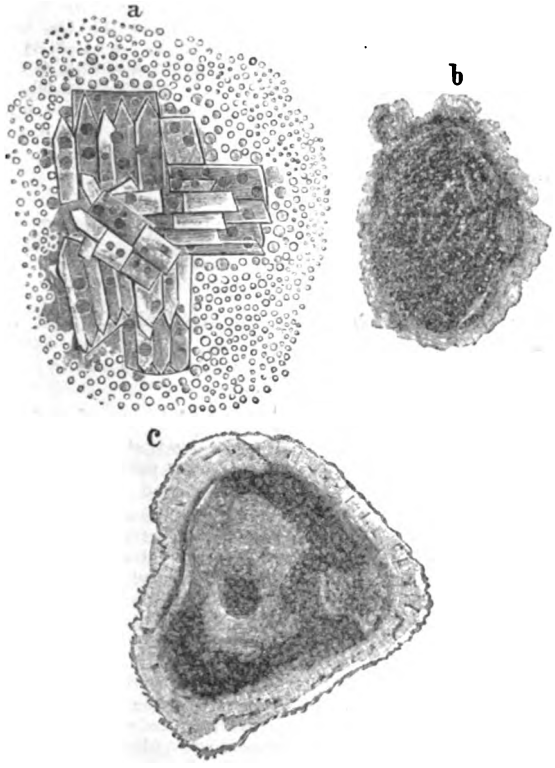
FIG. 7.

Globular urates which have developed from needle urates. The preparation (Fig. 2) was washed with water, and two drops of half normal solution of soda (NaHO) were added. In about half an hour, after the fluid had been reduced to about one-half by evaporation, the preparation presented the appearance shown (Fig. 7). The solution of sodium carbonate acts more slowly, but the result is the same. Enlarged 140 times.

as to the correctness of the observation. Both during the bath, and for a short time after, the tenderness on pressure and on movement is lessened. This is almost invariably the case and persists during the whole course of treatment. The use of "Kochbrunnen" baths hardly ever leads to an aggravation of symptoms when these are the result of acute gout or articular rheumatism, the sequelæ of which—viz., swelling and tenderness—may under ordinary circumstances persist for a very long time. A steady and progressive improvement is almost always the rule, relapses and exacerbations occurring only after some error in diet, especially over-indulgence in beer or wine, over exertion, or a sudden chill. Very different indeed is the influence of "Kochbrunnen" baths on persons suffering from chronic gout. Here we find that even after a few baths the symptoms are aggravated, not only in the parts previously affected, but even in parts previously free from pain or which have never been the seat of pain. E. Pfeiffer has had the same experience, but has never attempted an explanation. Such an explanation is, however, by no means difficult after my observations as to the behaviour of globular urates and needle urates as seen under the microscope. As I have already remarked, globular urates form, not only the first stage in the development of needle urates, but also the transition stage in their decomposition and dissolution (Fig. 7).

As already stated, the globular urates retain their globular form both in rheumatism and in chronic rheumatism. Hot baths tend to raise the temperature of the fluids in the tissues, strong alkaline waters, massage, &c., raise their alkalinity, the globular urates take up more of the base and become more soluble. As they dissolve improvement takes place. Attacks of acute articular rheumatism often leave obstinate sequelæ, which, however, gradually disappear under the influence of hot "Kochbrunnen" baths. The great tendency such patients exhibit of developing gouty deposits at a later period is probably due to the nutrition of the affected parts not being quite normal, and the alkalinity of the fluids being somewhat below normal as a result.

In acute gout uric acid crystals have formed during the attack owing to the slightly acid condition of the fluids in the diseased parts. As soon as alkalinity supervenes the bases combine with the uric acid to form globular urates. These may retain their globular form for some time during the continuance of the alkalinity of the fluids, and by accumulating in the lacunæ and lymphatic vessels may give rise to symptoms of inflammation and obstruction such as redness, œdema, &c. The great access of warmth due to the hot baths raises the temperature of the fluids; the large amount of acid salts eliminated by the perspiration and the absorption of alkalies increases the alkalinity of the tissue fluids and a more rapid circulation of the fluids bathing the globular urates occurs. By a further augmentation of these several factors or a long continuance of their action, or a frequent repetition of the same, the globular urates are finally completely dissolved and the last traces of the attack removed. In all the above instances the use of baths and strong alkaline mineral waters, &c., produces a steady improvement, and relapses hardly ever occur.



Very different, indeed, are the phenomena observed during the cure of cases where true gouty deposits of acid sodium urate, needle urates (chronic gout), exist. The increase of temperature, alkalinity, and increased circulation of the tissue fluids brought about by hot baths, strong alkaline mineral waters, massage, physical exercise, &c., renders the needle urates capable of combining with more sodium, whereby they become converted into globular urates, which in the early stages of the change are very minute or invisible. By accumulation and fusion they enlarge and may attain a size fifty times larger than a leucocyte. That under these circumstances obstruction of the lacunæ and lymphatic vessels, and hence stasis and its consequences, may be produced, just as occurred during the formation of the deposits, is obvious. Swelling, pain, œdema, and occasionally, though rarely, redness appear, and the patient—and often even the medical attendant—who does not know how to explain these phenomena, is surprised, and thinks that this long-vaunted remedy is aggravating instead of ameliorating his condition; nay, more, is even producing fresh pain in parts so far unaffected (latent gout). If the treatment is persevered with the new attack or exacerbation of symptoms may persist weeks, sometimes even longer. As soon as the treatment is interrupted or the baths only are stopped the dissolution of the needle urates soon ceases and with it the aggravation of the symptoms. The cause of the long continuance of the latter is to be found in the continual and persisting conversion of needle urates into globular forms, for although the latter are gradually being dissolved by the combined action of the above-mentioned factors, still fresh accumulations are constantly occurring in the neighbourhood of the deposits. This formation and destruction of the globular forms, and hence also the inflammatory phenomena, would continue in a greater or less degree until the last traces of uratic deposit have disappeared, provided the treatment is steadily persevered with. As this, however, would entail a course of treatment extending in some cases over several months, or even longer, a continuous course of treatment is not usually insisted on. As a rule the baths are suspended after from four to six weeks, and any deposits of needle urates still remaining are left to be attacked in the following year. In almost all cases a decided improvement takes place sooner or later after the bath treatment, and this is maintained so long as the patient is not exposed to fresh sources of danger. Frequently, however, even the most painstaking attention to a severe regimen is of no avail, fresh attacks constantly occurring as soon as the alkalinity of the tissue fluids falls to far below the normal standard and accidental exciting causes, such as a chill, unaccustomed indulgence in spirituous liquors, dinners, &c., come into play. In order to avoid any such

Digitized by Google

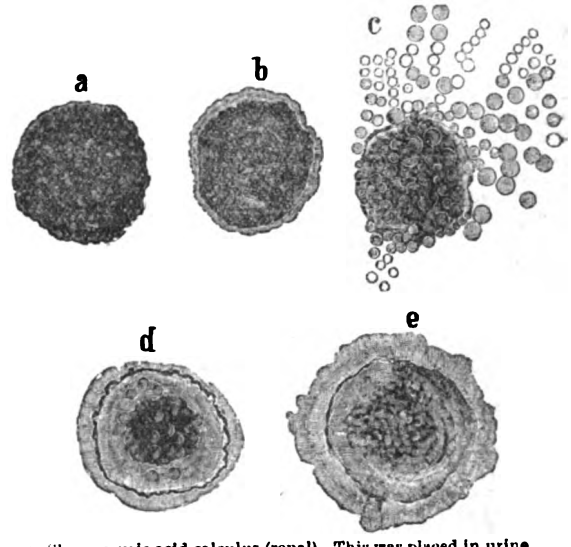
fresh attacks as far as possible it is advisable, as a prophylactic measure, to administer so much of some powerful alkaline muriated water from day to day as will suffice to keep the urine faintly acid, and occasionally even neutral or faintly alkaline in reaction.

Naturally the greater the amount of alkali introduced into the blood the more readily is the alkalinity of the fluids maintained at a level as nearly as possible approaching the normal. As, however, the introduction of large quantities of soda into the organism leads to the abstraction of an abnormal amount of salt (NaCl) from the latter (Stadelmann, Kleine, and Hartnack, and many others), it is necessary to add more salt to the ingesta. Finally, since the experience of English authorities (Duckworth, Thin, Moore, &c.) shows that lime salts hinder the elimination of uric acid, it follows that the patient should be ordered a mineral water which contains as much soda and salt and as little lime salts as possible. Of all known mineral waters, the Wiesbaden water satisfies these requirements most completely, as is clearly

FIG. 8.

a, Shows a mass of uric acid crystals from the urine of a man who suffers from renal calculus. After he had taken two bottles of Wiesbaden water daily for several days his urine became strongly alkaline and free from crystals. The mass of crystals was placed on a hollow slide and a few drops of his alkaline urine were added. The preparation was then placed under a glass bell to prevent evaporation. After two hours the mass was seen to be surrounded by innumerable large and small globular urates. *b*, Shows the same preparation two hours later, after the globular urates have been washed away. *c*, Fourteen hours later. The remaining mass consisted of a soft gelatinous mass. Enlarged 140 times.

shown by a comparison of the analysis of different mineral waters. These show, for instance, that the Wiesbaden water contains twice as much bicarbonate of soda, fourteen times as much salt, and one-fifth of the amount of lime salts contained in Vichy water.



It has often been my experience that an acute attack of gout was completely cut short by drinking daily from three to five bottles of this water; almost invariably such an attack is markedly shortened, a fact easily explained by the mode of origin of the attack (*vide supra*). In order to banish fresh attacks both of acute and chronic gout one bottle of this water daily will usually suffice in the majority of cases.

After the reading of the above paper a discussion ensued on the uric acid diathesis, in the course of which were made the following

Remarks by Dr. MORDHORST.—With regard to the remarks made by Dr. von Noorden, I am glad to find that he also considers an over-abundant meat diet deleterious in cases of uric acid diathesis. In this he agrees with the extensive experience of English authorities on the subject. This cannot, however, be said of him when he recommends calcium carbonate in the treatment of urinary concretions. Of the numerous English authors who warn us against using carbonate of lime and calcareous mineral waters extensively in such cases I will only mention the following. Duckworth, whose well-known treatise on Gout has recently been translated into German, says on page 342 of the English edition verbatim: "Waters much impregnated with lime or iron are distinctly unsuitable or apt to provoke gout. Sulphate of lime in water is especially noxious to the gouty. Both calcic and ferruginous salts tend to check elimination of uric acid and so are badly borne by the gouty." Thin[4] is of opinion that indulgence in waters containing large quantities of lime salts tends to predispose to gout.

Moore[5] points out that cerebral apoplexy, calcification of the aortic valves, and arterio-sclerosis are often the cause of sudden death in gouty patients. German authorities also participate in these views. Posner says[6]: "I have arrived at the definite conclusion, not experimentally, but by clinical

FIG. 9.

a, Shows a uric acid calculus (renal). This was placed in urine which had become alkaline after the use of Wiesbaden water. *b*, Shows it one hour later. *c*, After two hours more. *d*, The same, the globular urates having been washed away. *e*, The same eight hours later. experience, that waters which are rich in soda are borne much better than those rich in lime salts." E. Pfeiffer advises that in cases where the Fachingen water, which is rich in lime salts, is not well borne a less calcareous water should be recommended. Liebreich gives preference to those waters which contain the smallest proportion of lime salts. My own experience fully bears out the observation that waters which are rich in lime salts very often give rise to digestive disturbances, especially loss of appetite and constipation. Finally, when I consider that the urine may often be neutral, nay, even alkaline, at certain periods of the day—for instance, after meals—and that it becomes so all the more readily the greater the dose of calcium carbonate taken, I fail to see the advantage of treating uric acid concretions with carbonate of lime; for as soon as the neutral or alkaline tide in the urine sets in a turbidity due to phosphates and carbonates of lime is observed. What may be the consequences of this is shown by the analyses of 200

vesical calculi made by Kakula.[7] Nearly all these calculi consisted in the main of phosphates and carbonates of lime.

Finally, I would make a few remarks on Dr. Rosenfeld's fundamental rules for the treatment of uric acid diathesis. Rüdel was the first to draw attention to the solvent action on free uric acid possessed by solutions of urea. His statement, however, that of all the constituents of urine none possess this power, both in watery solutions and in urine, to such a degree as urea does is a direct contradiction to both Fürst's observations and my own. Fürst found that 100 c.cm. of a 0·5 per cent. solution of sodium bicarbonate dissolved 0·16 gramme; I found that 100 c.cm. of a 0·7 per cent. solution dissolved 0·2 gramme of uric acid. That is far more than a solution of urea will dissolve. A 0·7 per cent. solution of neutral phosphate or carbonate of soda has an even greater solvent action. Such being the case, there can be no advantage in administering urea internally with a view to increasing the solving power of the urine on uric acid when this object may be attained with far more certainty by means of sodium bicarbonate. Another ground for the use of urea, which, so far as I know, I was the first[8] to point out, is the property of urea of retarding or preventing the conversion of the urates in the urine into uric acid and sodium. In every solution of urates which does not contain urea the urates are immediately decomposed as soon as the solution is rendered acid by the addition of some acid. If urea be added to the original alkaline solution this decomposition is retarded and partly prevented, even though the solution be rendered decidedly acid. This would, I presume, be a reason for recommending urea to counteract the formation of uric acid concretions; the idea is, after all, rational. Nevertheless, I have not been able nor can I now bring myself to re-introduce into the organism one of its waste products. Rosenfeld has the merit of being the first to introduce urea and ammonium salts as a treatment for concretion. This merit would be all the greater should it be proved after several years' experience that these substances are in no way harmful to the organism and do not accelerate the appearance of uræmic symptoms so common in these cases, where the kidneys are mostly the seat of secondary inflammation. In his papers on the behaviour of ammonia salts in the animal organism Professor Rumpf has reported that ammonium carbonate when retained in the body for any length of time may lead to symptoms of poisoning. But why should we resort to substances whose harmlessness cannot but be doubtful when the normal urine points out to us what direction we should take in order to prevent the formation of concretions? Normal urine is by far less acid than that of people suffering from concretions The morning urine and that passed during digestion may be neutral, nay, even alkaline, provided meat has not entered too largely into the diet. It is the excess of bisodium phosphate over the monosodium phosphate in the urine which renders it neutral or alkaline. If sufficient quantities of sodium bicarbonate are administered we have it in our power to render even the most acid urine alkaline. Why do we not do so then? Because as soon as the urine becomes alkaline there is a precipitation of phosphate and carbonate of lime which may be deposited on any concretion already existing in the kidneys, renal pelvis, or bladder, and so may assist a rapid increase in their size. This can surely be the sole reason why von Noorden does not consider a long-continued alkalisation of the urine advisable. No other reasons can be brought forward. Several pupils of Stadelmann took daily doses of from 20 to 30 grammes (from 5 to 7½ drachms) of bicarbonate of soda or acetate for six weeks or longer. During the whole of this period the urine was alkaline, but no ill-effects were observed. Diarrhœa occurred only after very large doses, but ceased the moment the dose was reduced. The examination of the urine showed an excessive elimination of sodium chloride, proving that too much of this salt was being removed from the organism. This latter result was also obtained by Kleine[9] and Hartnack in their experiments, and they tried to explain it by the combination of the free hydrochloric acid in the stomach with the sodium. When it is desirable to administer large doses of bicarbonate of soda it is necessary to combine with them considerable doses of sodium chloride. Sodium chloride, like other neutral salts, has, in addition, the property of retarding the precipitation of uric acid crystals, a property which cannot be underrated in the treatment of uric acid concretions, as was first pointed out by Sir William Roberts. Large quantities of water tend to remove a great deal of acidity from the tissues, and also reduce the acidity of the urine; it is, therefore, well to recommend some mineral water which contains as much sodium bicarbonate, sodium chloride, and other neutral salts as possible. If, in addition, it contains only small traces of lime salts, and if no other beverage containing lime salts is taken at the same time, the urine thus made alkaline by copious use of such a water will, as a rule,[10] contain no deposit of phosphates. This, at least, is found to be so after using the Wiesbaden water. Other mineral waters, such as those of Fachingen, Bilin, Vichy, and Vals, do not possess this desirable advantage; the former contain too little sodium bicarbonate, all contain too little sodium chloride and other neutral salts, and far too much lime salts. As soon as one succeeds in rendering a slightly acid urine alkaline, or even only neutral, by taking large quantities of these waters, an immediate precipitation of the much dreaded phosphates occurs, whereas, as before mentioned, a copious use of Wiesbaden water produces absolutely no sediment.

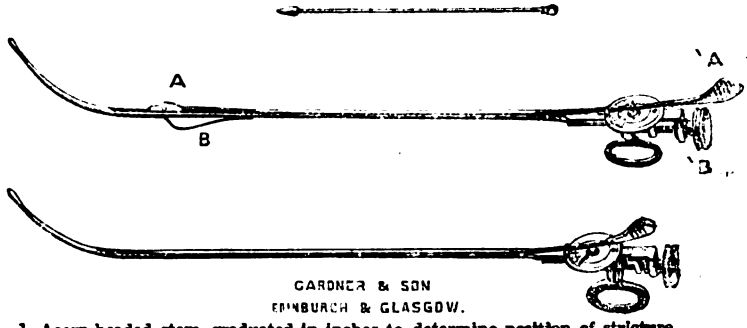
RESILIENT STRICTURE OF THE URETHRA AND ITS TREATMENT.

BY CHARLES WATSON MACGILLIVRAY, M.D., F.R.C.S. EDIN.,

SURGEON TO THE ROYAL INFIRMARY, EDINBURGH.

STRICTURE of the urethra is one of those ailments for which many methods of treatment have been suggested. Some of these are specially applicable for certain varieties—for example, in slight and early cases gradual dilatation is usually adopted; in cartilaginous stricture with fistulæ, external urethrotomy, and in cicatricial stricture near the meatus internal urethrotomy, while very frequently social reasons on the part of the patient and individual preference on the part of the surgeon determine the choice rather than the certainty that one method will give better results than another. In most cases whatever method be ultimately decided on one can confidently anticipate a considerable amount of relief from the distressing symptoms; but there are always certain varieties which are liable to lead to disappointment, and of all these, resilient stricture is perhaps the most annoying to both surgeon and patient. This form frequently comes on in comparatively young men, is very irritable, and associated with spasm, and although of small dimensions—forming, indeed, a mere ring round the urethra—often leads to complete retention, and presents considerable difficulties to the introduction of even the smallest instrument. When, however, an instrument has once been passed it is surprising with what ease larger instruments, even up to a No. 12 or a No. 18, may be introduced, and the patient goes away charmed with the speedy relief of all his discomforts. Unfortunately, in almost every case the result is the same—re-contraction takes place, and the patient returns shortly in the same state as before, whatever method of treatment may have been adopted.

The only two methods which in my experience have attained somewhat better results are those of Holt and Maisonneuve. These might be described as rough but effectual, and I was thus led to consider the special features of this form of stricture and wherein lay the difficulties of its treatment. Now, what strikes one most is the ease of dilatation and the rapidity of re-contraction, and in these respects it may be said to resemble very closely an india-rubber ring. One knows how easily such a ring can be dilated up to any size short of rupture, but how at once, on the removal of the dilating instrument, it returns to its



Digitized by Google

original dimensions; by analogy, therefore, gradual dilatation is evidently inapplicable to the treatment of this variety of stricture, but, on the other hand, if by any means one can divide such a ring it at once ceases to act. So long, therefore, as it remains whole it will contract concentrically; but divide it and any contractile power it possesses will rather tend to draw the cut ends apart, and so long as it remains severed it can never act as a constricting agent. Turning again to the resilient stricture, one has to consider what is the best method of severing the constricting band. Two methods at once suggest themselves. While gradual dilatation is useless, sudden dilation up to, say, No. 18, English scale, will tend to rupture the band, and of this method Holt's is the best example, not employed as usually recommended, by passing one dilator, followed by another of a larger size, but by dilating suddenly by means of a large dilator. This, though effective for the time being, is rough surgery, and does away with what Holt described as an essential feature of his method—namely, that the mucous membrane should remain intact, the submucous layer in which is situated the stricture being alone affected. If employed as here suggested the mucous membrane is sure to be torn, and one knows that a lacerated wound does not heal kindly, causing as it does a large amount of cicatricial tissue to form, which will reproduce the stricture. This being unsatisfactory the next method is internal urethrotomy, but before considering how this can best be performed let us return to the idea of the indiarubber ring and see how cutting acts upon it. Take a sharp knife and attempt to divide it, and you will be surprised to find how difficult this is to accomplish so long as the ring is unstretched; put it on the stretch, however, and a mere touch with a sharp edge will cause it to fly asunder. It is evident, therefore, that in order to perform internal urethrotomy satisfactorily, stretching the stricture is an indispensable preliminary; any instrument with merely a small concealed knife, however sharp, will not be sufficient.

Now what are the various forms of apparatus at present available? These may be broadly divided into those which cut from before backwards and those from behind forwards, and for accuracy and precision most surgeons will admit that the latter are preferable. It is always easy to make out the anterior end of a stricture, and by means of an acorn-headed stem or by other methods one can generally determine its posterior limit and be thus informed as to its exact position, size, and dimensions; one can therefore be much more accurate and limited in a cutting operation in the latter case than in the former. The disadvantage, however, of nearly all the instruments as yet invented for cutting from behind forwards is that from their size they are unsuited for any except moderately-sized strictures, such as will admit a No. 4 to No. 6 bougie, and that they do not introduce the principle of stretching as well as cutting. There are exceptions to this rule, Otis' urethrotome being excellent, but only for large-sized strictures, and Heron Watson's, on the principle of a Syme's staff, which from the employment of a large knife has the disadvantage of making it difficult to regulate the depth of the incision. It was evident, therefore, that what was required was an instrument which could penetrate the smallest strictures, would introduce the principle of stretching so that the least touch of the knife would thoroughly divide the constriction, while at the same time the cutting edge should be as limited as possible.

Of all the instruments with which a practised hand is likely to be successful in penetrating a tight stricture, none in my experience surpasses Heron Watson's graduated steel probe-pointed bougies and catheters, and I therefore took one of these as the ideal from which my instrument was to be evolved. My first idea was to modify Heron Watson's urethrotome, for undoubtedly the shoulder, as in Syme's staff, is useful in determining the exact site of the stricture, but I then thought that in cases of double stricture the simpler probe-pointed instrument would be more easily introduced, and there is really no difficulty in localising the position of a constriction. The instrument I finally decided on may be briefly described as follows. It is of steel, probe-pointed, and gradually increasing in size up to No. 5, the curve being that of an ordinary bougie; the under side is hollow, but with a slit of about two inches in length, this opening commencing just where the curve joins the straight portion. In this tube is a wire B, flattened like a watch-spring, opposite the slit, and fastened to the instrument at its point by means of a hinge. This can be projected to any desired extent in the form of a loop through the slit, by means of a screw in the handle 'B. On the upper surface is a groove, which becomes deeper just past the slit, and holds a small concealed probe-edged knife similar to that employed by Otis or Maisonneuve A. This can be protruded by pulling on the wire to which it is attached, which runs in the groove 'A. The straight part of the instrument is graduated in inches commencing at the near end of the slit, so that one can be sure that both the cutting and stretching apparatus are behind the stricture. The accompanying drawing, however, will better explain the mechanism of the instrument than any detailed description.

The method of application is as follows. The patient having been prepared for operation by rest in bed, dieting, and the administration of salol, a few drops of castor oil medicated with 5 per cent. of eucalyptus oil and 10 per cent. of cocaine are to be injected so as to render the urethra insensitive and obviate the necessity for a general anæsthetic. The exact position of the stricture having been ascertained, the urethrotome is to be introduced through the stricture so that the mechanism is behind it in the dilated portion of the urethra, the graduated scale on the stem enabling one to do this with accuracy. Then by means of the screw in the handle one projects the dilating loop to any desired extent. This from its shape can now, by slowly withdrawing the instrument, be made to stretch the stricture to its fullest extent, and on projecting the knife the slightest touch of the cutting edge is sufficient to thoroughly divide the stricture, and one is surprised to find how the instrument at once becomes loose in the urethra; the knife being now replaced in its groove, the instrument is withdrawn with the loop still projecting, so that any other constriction can be at once detected and divided. The operation is practically painless, the bleeding

1. Acorn-headed stem, graduated in inches to determine position of stricture. 2. Urethrotome as in use—(A) Probe-edged knife exposed by traction on handle 'A; (B) watch-spring loop, projected by screw at 'B (extent of projection shown at handle). 3. Urethrotome with mechanism concealed, as when introduced. Graduated in inches on shaft or near side of mechanism so as to be certain of being beyond the stricture. (The numbers are counted from above downwards.)

insignificant, and without difficulty graduated bougies of the full stretched capacity of the urethra, generally up to No. 18 or No. 20, can be at once introduced. The further treatment of the case can be carried out according to the individual views of the operator. As a general rule I prefer to tie in a large sized gum elastic catheter for three or four days, but I have also passed a catheter at regular intervals, and even allowed the patient to pass urine as required, with only in one instance urethral fever supervening.

The results of this method of treatment have been eminently satisfactory. I usually pass a large instrument within a fortnight of the operation and again after six weeks, as I am sure that in such cases the frequent passage of instruments only tends to set up irritation. In favourable cases I have been able to pass a No. 15 six months after the operation, no instrument except on the occasions I have already mentioned having been passed in the interval.

In this connexion there is one point in the treatment of stricture which I do not think has been sufficiently emphasised, and that is that whatever be the form we have to deal with or the method employed it is necessary to dilate the constriction up to the full stretched capacity of the urethra.

Digitized by Google

In any case the stricture is sure to quickly re-contract two or three sizes below its dilatation, so that if one is content to stop at No. 12, which may be taken as the usual unstretched capacity of the urethra, a rapid re-contraction takes place down to No. 9; but as No. 9 is below the normal capacity, force is required to expel the urine, posterior dilatation and irritation at the seat of stricture follow, and further constriction occurs; while if one dilates the urethra, say, up to No. 18, the rapid re-contraction narrows the lumen only to No. 15, and the urethra thus remains undilated and unirritated by the passage of urine, and further contraction is slow and very gradual.

Were I to have another instrument constructed there are various points in regard to which I think improvements might be made. First, I think it worthy of consideration whether a shoulder, as in Syme's staff, might not be an advantage, so as to rapidly indicate the position of the stricture; this, of course, would be placed at the proximal end of the dilating mechanism. Secondly, it might be advisable to reverse the positions of the dilator and knife, as it seems to be generally considered preferable to cut on the floor of the urethra rather than on the roof. Thirdly, the dilating mechanism is capable of improvement. It would be better if it was fixed, say, by parallel bars, as in a resistant stricture it gives somewhat, and then does not put the part as fully on the stretch as might be desired. And, lastly, although the probe on the edge of the knife is theoretically perfect, I think I have got better results with a knife without any blunt edge, its small size especially, when part of the cutting edge is occupied by the probe, resulting in a firm stricture not being thoroughly divided by the first attempt and requiring re-application.

I have now employed this instrument in about twenty cases of strictures in all parts of the urethra without any complication (except in one case, when slight shivering followed the first passage of urine), and with uniformly excellent results. I can, therefore, with the utmost confidence recommend it to the attention of the profession.

Edinburgh.

ON THE KNEE-JERKS IN DIABETES MELLITUS.

BY R. T. WILLIAMSON, M.D., M.R.C.P. LOND.,
MEDICAL REGISTRAR, ROYAL INFIRMARY, AND ASSISTANT IN MEDICINE, OWENS COLLEGE, MANCHESTER.

IT has been known for many years that the knee-jerks may disappear in diabetes mellitus.[1] In a paper published in 1892 I recorded the condition of the knee-jerks in fifty cases of diabetes mellitus; in one-half of the cases both the knee-jerks were absent.[2] I pointed out that previous statistics had varied considerably and that much difference of opinion existed respecting the prognostic value of this sign. Thus Bouchard found the knee-jerks absent in 36·9 per cent. of his cases, Auerbach[3] in from 35 to 40 per cent., Maschka[4] in 30·6 per cent., and Eichhorst[5] in 20·9 per cent. Soon afterwards Dr. Karl Grube, of Neuenahr, recorded[6] the results of the examination of the knee-jerks in a series of cases of diabetes; and an abstract of his paper appeared in THE LANCET.[7] Grube pointed out that in his cases (131 in number) the knee-jerks were absent in 7·6 per cent. only. In a second paper[8] Grube adds other cases, and states that in the combined series the knee-jerks were absent in 13·5 per cent.

The great difference between 7·6 per cent. (Grube) and my own results, 50 per cent., caused me to examine carefully the condition of the knee-jerks in a second series of cases in order to find out, if possible, the reason for this remarkable discrepancy in statistics. My results in the second series of 50 cases were, however, practically the same—the knee-jerks were both absent in 24, both were present in 23, and one was absent and one present in 3 cases. I may point out that the cases have been most carefully examined. In taking the reflexes the skin over the patellar ligament has been well exposed and the ligament struck directly, no clothing intervening. If no knee-jerk has been obtained in the ordinary way then Jendrassik's and Buzzard's methods have always been employed before the knee-jerks have been recorded as absent. (The patient is seated on a chair with his feet well in contact with the floor, and the knees bent at an angle just a little more than a right angle. He is made to look upwards, to link his fingers together and to pull tightly. The observer places one hand on the rectus femoris muscle and strikes the patellar ligament with a percussion hammer or stethoscope. If the slightest knee-jerk be present, a contraction of the rectus muscle will be felt.)[9] In many cases the knee-jerks appeared to be absent when an examination was made in the ordinary manner, but by the above method they were just obtained; and these cases, however feeble the reflexes, were classed amongst those in which the knee-jerks were present. Most of the cases examined were in-patients at the Manchester Royal Infirmary; they were examined repeatedly, often for weeks or months, and were then under the most favourable conditions for examination. Hence I feel justified in believing that my figures represent fairly accurately the condition of the knee-jerks amongst hospital patients who suffer from diabetes mellitus in Manchester. The following are my results in 100 cases:—Both knee-jerks were lost in 49; one knee-jerk was present and one absent in 6; and both knee-jerks were present in 45; total, 100. One of the cases in which the knee-jerks were present came under observation for a second time after an interval of eighteen months, and both knee-jerks were then absent. If this be added to the 49 cases, we have then the knee-jerks absent in 50 per cent. of the cases.

As above stated, Grube found the knee-jerks absent in only 7·6 per cent. of his first series of cases. What is the cause of this remarkable difference in statistics? I know Dr. Karl Grube to be such a careful and reliable observer that I can place the greatest confidence in his observations and, of course, am convinced that his statistics are correct with respect to the cases which he has examined. But I feel justified in believing my own statistics to be also accurate. The difference in results is interesting, and I believe the following to be the explanation. The 100 cases on which I have based my statistics have been almost all hospital patients in Manchester. They have been suffering mostly from a very severe form of the disease, generally with marked wasting. In a large proportion of cases the disease has been in a very advanced condition, and often the observations have been continued practically up to the last. (In 26 out of the 100 cases up to the last few days, and in a large number of cases up to the last few weeks of life.) The majority of the patients have been poor, hard-working people, and amongst the 100 cases there were very few examples of the mild form of the disease, which is met with in stout or gouty old people. As regards age, 81 of the 100 cases were under the age of fifty years. On the other hand, Dr. Karl Grube states[10] that the majority of his patients were over the age of fifty years, and it is well known that the severity of the disease is much less in patients over that age. Then, again, Dr. Grube is engaged in private consulting practice at Neuenahr—a small town in West Germany, much frequented by diabetic patients on account of its alkaline mineral waters, which are regarded as being of great value in diabetes, especially in the diabetes of gouty persons. Also his patients have probably been in a better social position and have lived under more favourable conditions of life than the hospital patients on whom my observations were made. Probably a large proportion of his cases would not be in the very last stage of the disease, otherwise they would not have been allowed to travel to Neuenahr. These I believe to be the causes of the difference of our results. I think it is a point of some interest that the knee-jerks should be absent so much more frequently amongst diabetic hospital patients, who suffer, as a rule, from the disease in its severest form. Eichhorst[11] has previously drawn attention to a difference between his hospital and private patients, the knee-jerks being absent in 42·9 per cent. of the former and 16·7 per cent. of the latter; but his observations were based on 36 private cases and only 7 hospital patients.

In the earliest stage of diabetes, even in its most severe form, I believe the knee-jerks would be found present as a rule; but in these cases they are very often lost later. I have frequently observed that in those severe cases in which the knee-jerks have been present when first examined, they have finally disappeared, if the cases have been under observation for a long period. Thus in the 100 cases which I have examined the knee-jerks, as above stated, were lost in 50 per cent., but in many cases I was not able to continue my observations up to the last. In 26 cases, however, in which I examined the knee-jerks up to the last day or last few days of life, I found they were both absent in 19 (= 73 per cent.), and present in 7; but in 4 out of these 7 cases they were exceedingly feeble. In the majority of cases I have found the knee-jerks to be absent during diabetic coma. Thus in 21 cases of diabetic coma which have come under my observation in Manchester the knee-jerks were absent in 18, but in 3 cases they were present (in 1 case half-an-hour before death, in another three hours before death, and in the third case at the commencement of coma). Generally the knee-jerks were absent for a long period before the onset of coma. In one case, however, they were present the day before the commencement of coma, but disappeared when the early symptoms of diabetic coma were observed. The following table (of 100 cases) shows that the knee-jerks are lost in a much greater proportion of cases under the age of thirty years than in cases over thirty years.

*Table Shewing the Relation between the Presence or Absence of Knee-jerk and the Age at which Diabetes occurs.**

Between the ages of	Knee-jerks absent.	Knee-jerks present.	Remarks.
10 and 20 years ...	13	3	Under the age of 25 knee-jerks were lost in 81 per cent.
20 and 25 years ...	9	2	
25 and 30 years ...	8	4	—
Totals	30	9	Under the age of 30 knee-jerks were lost in 76·9 per cent.
30 and 40 years ...	8	10	—
40 and 50 years ...	5	14	—
50 and 60 years ...	9	4	—
Over 60 years ...	3	8	—
Totals	25	36	Over the age of 30 knee-jerks were absent in 40·9 per cent.

* This table is based on another series of 100 cases.

As regards the cause of the loss of knee-jerks in diabetes, the frequent association of pain, numbness, muscular tenderness, and cramps points to an early peripheral neuritis;[12] and a few cases have been recorded in which well-marked typical motor and sensory symptoms of peripheral neuritis have been present;[13] also in a few cases examined pathologically parenchymatous neuritis of the peripheral nerves (branches of the anterior crural) has been found.[14] But frequently when the knee-jerks are absent there are no other indications of slight peripheral neuritis, and the peripheral nerves may be normal on pathological examination. I have examined the small peripheral nerves in three cases of diabetes mellitus in which the knee-jerks were absent—in two cases the branches of the anterior crural in the thigh, in the third case branches of the anterior tibial. In all three cases the nerve fibres appeared normal. I have found slight changes in the posterior columns of the spinal cord in two cases of diabetes.[15] Similar changes have also been recorded by Sandmeyer,[16] Leyden,[17] and Minor.[18] In one of these two cases the knee-jerks were absent, the peripheral nerves examined (branches of the anterior crural) were normal, but changes were found in the posterior columns extending down to the upper lumbar region. In other cases I have found the spinal cord normal, and many cases have also been recorded in which the knee-jerks have been absent, and yet the cord has been normal on pathological examination. Nonne has reported a case of diabetes complicated with progressive muscular atrophy.[19] Pathological examination revealed chronic anterior poliomyelitis. The nerve cells and fibres of the anterior horns of grey matter were markedly degenerated at all parts of the cord: at the latter stage of disease the knee-jerks were absent. In one case in which the knee-jerks were absent during life, I found both the smallest peripheral nerves (branches of anterior crural) and the spinal cord normal on pathological examination, and others have had similar results.[20]

The changes which have been found in the cases just mentioned—i.e., changes either in the spinal cord or peripheral nerves—have been sufficient to explain the loss of knee-jerks in these cases. But in other cases, in which both cord and small peripheral nerve present no recognisable changes histologically (and probably these are more numerous than the former), some other explanation is needed. Either changes (not yet described) are present in the most minute nerve fibres and motor end-plates or the loss of the knee-jerk is due to some functional change in the spinal cord, peripheral nerves, or muscles. Marinesco[21] has recently recorded a case of diabetes in which both knee-jerks were absent, but after an attack of hemiplegia the knee-jerk returned on the paralysed side, the case being analogous to that of tabes reported by Dr. Hughlings Jackson and Dr. Taylor, in which, after an attack of hemiplegia, the knee-jerk returned on the paralysed side.

Conclusions.—1. In Manchester, amongst hospital patients suffering from diabetes mellitus, the knee-jerks are lost in from 49 to 50 per cent. of the cases. These patients mostly suffer from a severe form of the disease; 81 per cent. are under the age of fifty years; frequently there is great emaciation, and the cases are often at an advanced stage. 2. In private practice, amongst patients who live under more favourable conditions, and in the milder forms of the disease occurring in gouty or well-nourished people over the age of fifty years, I believe the proportion of cases in which the knee-jerks are absent will be much less (knee-jerks were absent in 16·7 per cent. of private patients—Eichhorst; knee-jerks were absent in only 7·6 per cent.—Grube of Neuenahr—the patients being mostly over fifty years). 3. The knee-jerks when present at an earlier period are frequently lost or diminished later. During the last few days of life the knee-jerks are lost in 73 per cent. of hospital diabetic patients in Manchester. 4. They were lost in eighteen out of twenty-one cases of diabetic coma (86 per cent.). 5. Amongst diabetic hospital patients the knee-jerks are more frequently lost under the age of thirty years than over thirty. 6. Since the course of diabetes mellitus depends on so many circumstances, it is somewhat difficult to estimate the exact prognostic value of one symptom, which is occasionally absent even up to the last; but the above facts and considerations seem to show clearly that the loss of knee-jerks is more frequently associated with unfavourable prognostic indications.

CASE OF PYO-SALPINX AND OTHER CASES IN WHICH INJECTION OF SALINE SOLUTION WAS USED.

BY W. C. ARNISON, M.D. DURH.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF DURHAM, AND LATE SENIOR SURGEON TO THE INFIRMARY, NEWCASTLE-ON-TYNE.

CASE 1.—A woman, aged thirty-two years, married, was admitted into the medical wards of the Newcastle Infirmary, under Dr. Philipson. Shortly after her admission the case was diagnosed as pyo-salpinx, and she was transferred to my ward for operation. She was in a very low condition, with high temperature, and nocturnal delirium. The operation

was performed on Feb. 14th, 1896 The abdomen was opened by an incision through the substance of the left rectus muscle. The usual sausage-shaped tumour was found, tense, and freely adherent. The adhesions bled freely, as they were separated, and the cyst burst, discharging very fœtid pus into the sponges placed in the pelvis. After the removal of the left appendage the right was found in the same condition and was removed. It also burst and discharged similar fœtid pus. As contamination of the peritoneum could not be avoided, it was well sluiced with 1 in 10,000 sublimate solution, and carefully cleansed, a glass drainage tube being left after securing all bleeding points. The patient bore the operation well. An hour afterwards three ounces of blood were drawn off through the tube, but after that nothing of consequence came away. Next morning she was apparently going on well, but twenty-four hours after the operation she suddenly collapsed, with an almost imperceptible pulse; the face was pallid and shrunken, and there was every appearance of impending death. Two drachms of an almost colourless fluid were drawn off through the tube, thus proving the absence of internal bleeding. The median basilic vein was promptly opened, and three pints of normal saline solution at a temperature of 112° F. were slowly thrown in by gravitation. The effect was immediate, the pulse became steady and easily counted (150). A quarter of an hour after the injection she vomited some bile-stained fluid; this was followed in half an hour by a well-marked rigor, with sweating. The temperature was 102° F., rising in a short time to 104°. Four hours afterwards the pulse had fallen to 115, the patient had greatly improved, and she said that new life had been put into her. The improvement continued, but her recovery was retarded by the abundant discharge of pus of the same fœtid character as that in the tubes at the operation. The pelvis was repeatedly washed out daily with Condy's fluid, but for some days without effect, when diluted sulphurous acid was tried, yet still without effect; but the fœtor quickly yielded to crystallised iodoform thrown down the tube, which was soon afterwards withdrawn, as the discharge ceased, and recovery went on slowly but without further drawback.

It is worth noting that the loss of blood at the operation was not excessive, and did not continue long afterwards. The collapse on the following day seems to have been due to loss of vaso-motor influence following on the abdominal operation. The patient was, in fact, bleeding to death into the vessels of her own abdominal viscera. The saline injection kept the circulation going until it was able to draw upon the blood temporarily lying in those vessels, and restore it to the general circulation.

The injection of saline solution has been resorted to rather freely at the Newcastle Infirmary, and in most cases with admirable effect. The two following cases are examples taken from several others in my own wards.

CASE 2.—A woman was admitted with a large collection of pus in the knee-joint, following white leg after confinement. The joint was incised in two or three places, washed out, and drained, with relief, but a day or two afterwards she was apparently sinking. After injection she quickly rallied, and for a time improved, but the joint was disorganised and she began to lose ground. Amputation high in the thigh was performed, when she nearly died on the table; but injection of the saline solution, which had been got ready in anticipation, brought her round, and she rapidly recovered.

CASE 3.—A man aged fifty years had his hand caught in machinery and was carried five times round a revolving shaft. He was admitted with fracture of several ribs on the left side, fracture of the sternum, and fracture of nearly every rib on the right side, so that the right side of the chest sank in with each inspiration. There was extensive subcutaneous emphysema on the right side, and the right arm was smashed, so as to require amputation through the humerus. There was extreme pallor and depression, but the pulse was fairly good, so I ventured to amputate; but we had saline solution ready, and before closing the stump forty ounces were poured into the open end of one of the veins, with instant good effect. No bandage or plaster was applied to the chest. A month after the accident he was nearly well, and ultimately recovered perfectly.

I am indebted for the notes of the cases to my late house surgeon, Dr. R. W. Morgan.

Newcastle-on-Tyne.

THE THERAPEUTICAL ASPECTS OF TALKING, SHOUTING, SINGING, LAUGHING, CRYING, SIGHING, AND YAWNING.

BY HARRY CAMPBELL, M.D., F.R.C.P. LOND.,
PHYSICIAN, NORTH-WEST LONDON HOSPITAL.

THE respiratory movements have wide-reaching effects. They not only lead to the flow of air to and from the lungs, but they profoundly influence the circulation of the blood and lymph; they also affect the functions of the abdominal and pelvic viscera by rhythmically compressing and dislocating them. Now, these movements are liable to constant modification in the physiological acts of talking, shouting, singing, laughing, crying, sighing, and yawning (as also in the occasional and semi-pathological acts of sneezing, coughing, vomiting, and hiccoughing), and it therefore follows that these acts are more far-reaching in their effects than would at first sight appear, and hence are worthy of our careful study. This will the more readily be granted when it is added that they affect the body, not only by modifying the respiratory movements and thus producing the effects already mentioned, but by involving the expenditure of a considerable amount of neuro-muscular energy, and by inducing definite psychic phenomena which themselves have their physical accompaniments. In brief, any one of these acts—e.g., singing—causes (*a*) a modification in the circulation of blood and lymph; (*b*) an alteration in the functions of the abdominal and pelvic viscera; and further leads to (*c*) a considerable discharge of nervous and muscular energy; and to (*d*) numerous changes (muscular, glandular, and other) throughout the body in consequence of the attendant psychic change.

Seeing, then, how far-reaching are the effects of these several acts, and remembering how large a part they play in normal life, we may safely conclude that they influence the functions of the body beneficially, and that an undue interference with them is injurious. One is apt to forget how strong is the instinct to shout and sing, laugh and cry. It is especially noticeable in the savage and in the child. If these instincts are unduly repressed in the child he is sure to suffer. Crying should certainly be restrained within limits, but there can be no doubt that it is primarily physiological, not only favouring the proper expansion of the lungs and accelerating the circulation, but deadening the effects of pain and relieving nerve tension (especially in woman). Rosbach thinks it not improbable that many evils which manifest themselves in later life, such as chlorosis, contracted chest, and the phthisical habit, "may take their origin in the practice of mothers to stop their infants from screaming by soothing them to sleep in their arms or by stupefying rocking in the cradle."[1] It is well known that children show a strong instinct to chatter and sing the first thing in the morning, and it should be allowed full vent as far as is practicable. The shouting which young people indulge in during their play is quite remarkable and is manifestly physiological. The same tendency to shout is observed in young adults, especially among the poorer classes in holiday time. Though from the physiological point of view justifiable, and even beneficial, the noises they make are certainly not always pleasing, especially to the sensitive nerves of the cultured, amongst whom this instinct is consequently suppressed, though whether altogether to the gain of the individual is questionable.

The various acts referred to will now be considered individually.

Talking.—As regards the psychic aspect of talking, thought becomes much more vivid if it finds expression, whether in speech, writing, music, or artistic production, than if it remains unexpressed. The physical effects of thought are more pronounced in talking than in writing. The cortical nervous discharges underlying it send a stream of energy towards the muscles involved in speech and gesture, and both voice and gesture can be modified to convey subtle shades of thought and feeling which cannot find expression in writing. The very expression of these refinements enhances the vividness and intensity of mentation. Talking is for this reason stimulating, and its influence in

[1] Von Ziemssen's General Therapeutics, vol. iii., p. 581.

Digitized by Google

this respect is in a measure proportional to the gesture accompanying it. Few things are more calculated to stimulate the body, to rouse it from lethargy, than "animated" conversation. In talking, as in laughing, shouting, singing, and crying, inspiration is short, while expiration is prolonged, the exit of air being checked partly by obstruction in the glottis and partly, perhaps, by the action of the inspiratory muscles. The actual amount of work done in talking is far more than might at first sight be supposed, and should always be taken into account in reckoning up the quantity of exercise taken during the day. The amount of talking done by barristers, politicians, and others enables them to dispense largely with exercise as ordinarily understood; for not only do they in this way expend a considerable amount of muscular energy, but they experience the manifold advantages of active respiratory movements continued for long periods together; indeed, I believe talking to be distinctly conducive to longevity. That talking involves a considerable expenditure of energy is shown by the exhaustion which it induces in those who are nervously run down. Such are often greatly exhausted, even after a moderate day's talking. This exhaustion is due to mental as well as to muscular expenditure; indeed, in the very neurasthenic the bare process of thought may be an effort and the mere effort to think may alone cause exhaustion; and if such is the case, how much more likely is the putting of thought into speech to do so, seeing that, apart from the muscular expenditure involved in speech, thought is so much more intense when spoken than when unexpressed. Talking is a beneficial exercise in heart disease, especially in those forms in which the blood tends to be dammed back upon the lungs. The good effect is here doubtless due to the increased amplitude of the respiratory movements and to the help thus afforded to the pulmonary circulation. It is for this reason that I always encourage talking in those suffering from passive engorgement of the lungs. "The breathlessness due to dilatation of the heart," observes Sir William Broadbent, "is often relieved by exercise of the voice. I have met with numerous instances in which a clergyman has climbed into the pulpit with the utmost difficulty, and has not only preached a sermon comfortably, but has been all the better for it."[2] The good result, I take it, in these cases is attributable to the deep inspirations required by the loud voice necessary to fill a large building.

Shouting.—The psychic accompaniment of shouting is essentially emotional. Emotion is not only expressed, but sustained, and, indeed, intensified by it. Thus the shouting of children at play, itself the outcome of exuberant emotion and pent-up neuro-muscular energy, enhances the emotional outburst. In like manner the hurrahs of an applauding multitude, the cry of the huntsman, the war-whoop of the savage, the yells of an attacking force, may so exalt emotionality as to induce a condition bordering on ecstacy. A further effect of shouting is to dull sensibility, the emotional exaltation which it provokes, and the voluminous discharge of neuro-muscular energy accompanying it, inducing a corresponding depression in the sensorial sphere. It is on this principle that groaning, and still more the shriek of acute agony, bring relief. The mere sound produces a similar effect by violently energising the acoustic centres.[3] The shouting and gesticulation which accompany an outburst of passion act physiologically by relieving nerve tension; and, indeed, as Hughlings Jackson has suggested, swearing may not be without its physiological justification. Passionate outbursts are generally succeeded by a period of good behaviour, and, it may be, improved health. One frequently notices this in children, and I have also observed it in the adult. It is possible that the outbursts of irritability observed in disease, as, for instance, in gout, have their physiological as well as their pathological aspect. As regards the modifications in the respiratory movements caused by shouting the important practical point to notice is that they are increased in depth. Hence shouting favours the development of the lungs and accelerates the circulation of blood and lymph.

Singing.—Singing, like shouting, is more emotional than intellectual, the degree of emotion called forth depending upon the extent to which the individual throws himself into the spirit of the song. The nature of the attendant emotion varies of course considerably, and there is a corresponding variability in its physical correlatives: if the theme of the song be joyous the proper rendering of it is highly stimulating. In singing there is a great disproportion between inspiration and expiration, the former being much the shorter. Moreover, during these long expirations the glottis is constricted, and the free egress of air being thus prevented intra-pulmonary air tension rises and frequently the flow of blood to and from the right heart is impeded, but this temporary retardation of the blood-flow may be more than compounded for by the acceleration which takes place during the succeeding deep inspiration. The obstruction of the glottis increases as the scale is ascended, and seeing that the expiratory force employed in the delivery of the upper notes is, for the most part, greater than that employed in the production of the lower, it follows that high singing, especially if *fortissimo*, impedes the circulation more than low singing. From the medical standpoint singing is a most important exercise, both by virtue of its influence on the emotions, on the respiratory movements, and on the development of the lungs. The good average health enjoyed by professional singers is in large measure attributable to the mere exercise of their calling.[4] Such therapeutic importance do I attach to singing that I recommend it wherever opportunity affords. It is especially useful in defective chest development and in chronic heart disease. Oertel speaks enthusiastically of the beneficial influence of singing on the general health, and especially on the lungs, and he refers to the fact that almost all eminent singing masters can tell of serious cases of lung disease which have been cured by their method of singing. He thinks there can be no doubt that weak chests of various kinds can be greatly improved by it, and he would even appear to include phthisis. "In consequence of the reports sent in from various quarters on the healthy influence of singing on the respiration and circulation and on the strengthening and nutrition of the lung, the practice of singing has been introduced even into prisons in order to antagonise pulmonary consumption, which generally develops in a short time amongst the convicts. The method of singing devised by Fried-Grell is especially adapted for our national schools and ought to be generally introduced, like gymnastics, from a sanitary point of view."[5]

Laughter.—The psychic accompaniment of laughter being joyous emotion, its effect is stimulating, and it has been truly said that the man who makes us laugh is a public benefactor. Its beneficial effect on the body is illustrated by the saying, "Laugh and grow fat." The expiratory act in laughter is greatly prolonged, and, the glottis being partly closed, intra-pulmonary tension is increased; and thus in excessive laughter there may be considerable impediment to the flow of blood through the lungs, as shown by the turgid head and neck. This disadvantage—for in most cases of heart disease it is a disadvantage—is far more than compensated for by other effects, foremost among which must be reckoned the deep inspirations which separate the individual paroxysms.

Crying.—In thinking of the term "crying" one must distinguish between the mere shedding of tears, and weeping accompanied by sobbing. In the one the effects are limited, while in the other the entire body may be convulsed. I have already referred to the beneficial effects of crying in children. The crying of the infant is peculiar. Expirations are prolonged sometimes for as much as half a minute, and are interrupted by short inspirations. During the expirations the glottis is contracted and the intra-pulmonary pressure rises considerably. Not only is the pulmonary circulation thereby greatly impeded, as shown by the swollen veins of the head and neck, but bronchial mucus, flatus, and other noxious matters are evacuated. The paroxysm is succeeded by rapid deep respirations, which restore the equilibrium of the circulation. Women likewise often derive benefit from "a good cry"—the profuse flow of tears lessens blood-pressure within the cranium; the voluminous discharge of nerve energy relieves nerve tension; the sobbing movements of respiration influence in a very decided and doubtless beneficial way the circulation and the movements of the abdomino-pelvic viscera; while the widespread contraction of the muscle system has probably also a good effect.

[2] THE LANCET, April 4th, 1891, p. 798.

[3] A famous quack extracts his patient's teeth to the blare of trumpets and the boom of the big drum.

[4] The splendid chest development of public singers is, of course, not entirely attributable to the constant exercise of the voice, since no one can attain a high excellence without having a good chest development in the first instance. It must also be observed that every singer who attains to fame is careful to lead a healthy life.

[5] Von Ziemssen's General Therapeutics, p. 582.

Digitized by Google

How pronounced are the dynamic effects induced by completely abandoning oneself to a fit of crying is shown by the exhaustion which it entails. It is partly through this exhaustion that crying induces sleep; we hear of "crying oneself to sleep," though this must be but a very crude explanation of the phenomenon. The tendency of women to cry should, of course, be kept within proper bounds, but certainly harm may result from its complete suppression, as Tennyson recognises in the line—

"She must weep or she will die."

It is said that women who are able to find relief in tears keep their youth longer than those who repress them. The internal cankering action "like a worm i' the bud" of pent-up emotion is not only a beautiful poetic conceit, but a profound physiological truth. In short, strong emotion should receive expression—"give sorrow words."

Sighing.—"A sigh is a deep thoracic respiration, with retraction of the abdomen."[6] The retraction of the abdominal muscles leads to a compression of the splanchnic veins. This compression is probably increased by slight descent of the diaphragm. The blood is thus pressed out of those veins into the right heart, and the flow into this chamber is further favoured by the deep inspiration which also aids the circulation through the lungs. Now Hill has pointed out[7] that the blood accumulates in the splanchnic veins in syncope, and that "a deep sigh is the first obvious sign of improvement." That the act of sighing in syncope has the effect maintained is shown by the observation of Stephen Hales. He noticed that the arterial blood-pressure in horses rises considerably on deep sighing and that the same effect is produced in dogs by firmly pressing the abdomen.[8] The sigh of syncope is comparatively rare. A much more common cause of sighing I believe to be shallow breathing, however induced. Thus sadness and a sense of weariness or boredom are wont to be attended by shallow breathing, and in all of them sighing is frequent. In consequence of this shallow breathing blood-aeration lags behind, and the blood tends to accumulate in the right heart and systemic veins. The sigh benefits by promoting the aeration of the blood and quickening the pulmonary circulation, and it is for similar reasons that sighing is apt to occur during a state of "breathless attention"—when the attention, i.e., is so strained that one forgets, as it were, to breathe adequately.

Yawning.—It is difficult to describe accurately this act. A deep and prolonged inspiration is taken through the mouth and nose, the mouth being widely opened and the nares dilated. The opening of the mouth is effected by a strong tonic contraction of the depressors of the lower jaw and by the extension of the head and consequent elevation of the upper jaw. At the same time the limbs and trunk are "stretched." There is, in short, a widespread tonic contraction of the muscle system. This continues and indeed reaches its climax during the expiratory portion of the act, the mouth being kept open till towards the end of it. The expiratory blast is directed solely through the mouth owing to the elevation of the soft palate, and the vocal cords approximate, a characteristic sound being produced in the larynx, while there is a peculiar contraction of the muscles at the back of the throat the nature of which I do not understand. There can be little doubt that one of the objects of yawning is the exercise of muscles which have been for a long time quiescent, and the acceleration of the blood and lymph flow which has in consequence of this quiescence become sluggish. Hence its frequency after one has remained for some time in the same position—e.g., when waking in the morning. Coöperating with this cause is sleepiness and the shallow breathing which it entails. This factor, as well as muscle-quiescence, is apt to attend the sense of boredom which one experiences in listening to a dull sermon. Hence it is that the bored individual is apt to yawn. As in the case of sighing, the deep breath which accompanies the act of yawning compensates for the shallow breathing which is so apt to excite it. I am unable to offer any explanation of the yawning—or, rather, gaping—which is induced by exhaustion from want of food. This mere gaping is, however, quite distinct from yawning, which is a much more complex phenomenon. Allied to yawning is a modification of the breathing which is apt to occur during sleep. A deep breath is taken more or less suddenly, and this is followed by a long-drawn-out expiration with probably closed glottis and a groaning sound. This kind of breathing has certainly some physiological import, but what it is I cannot say.

AN UNUSUAL CASE OF PARALYSIS OF THE OCULAR MUSCLES.

BY LESLIE BUCHANAN, M.B. GLASG.,
PATHOLOGIST AND CLINICAL ASSISTANT, GLASGOW EYE INFIRMARY.

THE patient who was the subject of this unusual train of symptoms came to me first on Oct. 31st, 1894, complaining of headache, giddiness, and difficulty of vision, and was accompanied by her sister whose support was necessary to enable her to walk at all correctly. The history of her condition was that headache was the first evidence of any disorder and appeared just thirteen days before, being closely followed by giddiness, and that difficulty of vision was the last symptom to appear. The past history of the patient was practically without blemish, she not having had any serious or prolonged illness in her life. There was no evidence of gout, rheumatism, syphilis tuberculosis, or, indeed, of any dyscrasia, and the patient was not at any time either neurotic or hysterical. There was no history of any injury at all likely to give rise to such symptoms as the patient complained of. The family history of the patient was of the very soundest description, no bodily habit or tendency in any way prejudicial being transmitted, so far as could be found. There had not been any nervous disease in the family. When first seen, the patient, who was about thirty years of age, was, apart from the aforementioned symptoms, in perfect health, neither anæmic nor plethoric, although well nourished; and further she was of sober manner and quiet demeanour. She stated that her headaches were almost entirely frontal, not tending to one side more than the other, and that they generally began with pain in the eyes. They were, further, distinctly worse after using the eyes for a time, ceasing at night, but often being present on waking in the morning, more especially if she had been working at her employment—i.e., dressmaking—the previous night. The vertigo was of a general nature, and there was no inclination to fall to one side more than the other. The patient could stand well with the eyes closed, the feet together, and the hands raised high above the head. She could not "walk a line" at all well, and any effort to hold on to or grasp anything evidently increased the difficulty of the process, which seemed to indicate that visual effort was—in part at least—the cause of the deficiency. The visual disturbance appeared to be difficult to define as it tended in no very special direction but resulted, somehow, in confusion (the patient had never noticed that she saw objects doubled until, by the usual methods, it was pointed out to her). It was manifest, on examination, that there was a nearly complete paralysis of the external rectus muscle of the right eye, this muscle being unable to turn the eye outwards further than the middle line, there being, however, no convergent strabismus at this date. Diplopia was, of course, homonymous and was present even when an object was held 15° to the left of the middle line at 10 ft. distance. Ophthalmoscopic examination revealed neither error of refraction nor change in any degree of the fundus of either eye, and there was no evidence of internal ophthalmoplegia. The fields were normal both for colour and white light. The knee and other reflexes were examined, but no evidence of nervous affection was found in any part. Examination of the general organs proved to be entirely negative, and inquiry failed to elicit evidence of any functional inaccuracy or disorder; indeed, there appeared to be absolutely no signs, other than those before mentioned, of any disease. It seemed highly probable, then, that both headaches and vertigo were the results rather than the companion symptoms of the paralysis. A guarded prognosis was given, complete ocular rest was ordered, and the use for a prolonged period recommended of a mixture containing the iodide and bromide of potassium with nux vomica. As regards the course of the disease it was found to be moderately rapid, for on Nov. 14th the paralysis was complete, there being

Digitized by Google

considerable convergent strabismus. The headaches were now, on account doubtless of the cessation of visual effort, much less severe and less frequent, but the vertigo continued in much the same degree. On Dec. 26th the state of matters was entirely changed, for now the right eye had entirely regained its powers of movement, whereas the left external rectus muscle was entirely paralysed, there being marked left convergent strabismus. As the patient could give no account of the date on which the change had occurred, but thought that the right eye was still affected, it is probable that an overlapping, as it were, had taken place, the left eye beginning to be affected before the right was entirely well. The change and the rapidity of its occurrence seemed to justify the giving of a slightly more favourable prognosis, as it was considered probable that any paralysis from a grave lesion would hardly run such a course as this. The left eye ultimately completely recovered its powers of movement, &c., so that by the end of January, 1895, the patient was able to return to her regular work without any inconvenience. She was seen again in March, 1895, in perfect health, and in this state she remained over two years ago, when she was last seen.

Before proceeding to discuss the probable cause of this peculiar train of symptoms it may be wise to review briefly the various causes of ocular paralysis. An ocular paralysis may be of either orbital, basal, nuclear, or cortical origin. Orbital paralyses are almost always accompanied by some local sign, such as pain, swelling, &c.; basal paralyses are exceptionally rarely isolated, but they generally implicate several nerves; nuclear paralyses are characterised by non-recognition of double images and the occurrence of a condition of somnolence; and cortical paralyses are generally or always conjugate—namely, associated movements are implicated. Writers on the subject are agreed that syphilis is the most common cause of ocular palsies, and, further, that in this condition the third nerve is affected in preference to the fourth and sixth. Some writers state that one-half of the total of ocular palsies are syphilitic. Next to syphilis spinal disease is either accompanied or preceded by an ocular palsy; but it must be remembered that spinal diseases are most frequently found among the syphilitic. In spinal affections ocular symptoms are frequently noticed a long time prior to the date of the discovery of the symptom characteristic of spinal disease, and also it is known that such ocular symptoms, although they may be permanent—more especially optic nerve changes and other symptoms in later stages—are often transitory and variable, ultimately passing away completely. Some difference of opinion exists as to which ocular nerve is most frequently affected in such cases, but Gowers, Berger, De Watteville, Landolt, and others are agreed that in tabes and insular sclerosis the rectus extensor—i.e., the sixth nerve—is most frequently paralysed, whereas Pierre Marie states that the third nerve is most frequently affected. The next type of ocular paralysis frequently mentioned is the so-called rheumatic type, the existence of which is doubted by some writers, notably by Jeffries,[1] who states that "in 60 cases or so there is but one which can fairly be considered as belonging to this group, if it exist" and he seems to consider them as syphilitic. Noyes mentions rheumatic paralysis as being difficult to prove. In addition to these general conditions causing, as well as predisposing to, paralysis, many other affections, such as meningitis in children, especially often of tuberculous origin, cerebral abcess, softening, tumour, hæmorrhage, etc., orbital tumour, abscess, injury, etc., may give rise to loss of function of one or more of the ocular muscles. Variable paralyses are usually of central origin and most frequently precede spinal lesions, as Jeffries[2] says "Transitory paralyses in the syphilitic are strongly suggestive of tabes to follow."

Search has failed to bring to light any record of a case exactly parallel to this present one, but it may be mentioned that in July, 1895, I saw at the Eye Infirmary, Glasgow, a young woman suffering from paralysis of the right external rectus muscle, who stated that, "a few weeks before, the left eye had been affected in the same way." No note of this fact could be found, and the patient was ultimately lost sight of. In the present case, then, we have to account for a paralysis of one muscle slowly becoming complete and rapidly recovering, followed by an exactly similar paralysis of the homologous muscle on the opposite side, also ending in complete recovery. Generally speaking, the total absence of any sign of other disease or implication of other nerve, points to freedom of the orbit and base of the skulls from any lesion. The absence of evidence of conjugate paralysis indicates freedom of the cerebral cortex, whilst the variable nature of the paralysis and the non-recognition of the double images seem to indicate that the lesion was of nuclear origin. The history of the patient excludes syphilis, and, to a less degree it is true, spinal disease, for although it is now more than two years since the last symptom of the affection passed away, it is well known that sometimes premonitory symptoms of spinal lesions may be present and may have been present, but have passed away many years before the characteristic symptom appears. In the case, however, of a young female, free from both syphilis and tuberculous disease, spinal disease is, although not unknown, not common. Rheumatism was practically unknown in this patient's family; and further, as a rheumatic paralysis seems to be the result of a periostitis round the foramen or passage whereby the cranial nerve (such as the seventh nerve) leaves the cranial cavity, it is not probable that such a lesion could account for the train of symptoms here present, especially without giving rise to any other symptoms.

A few words may be of service here regarding the position and relations of the sixth nerve and its nucleus. The nucleus of the sixth nerve lies in the floor of the fourth ventricle, superficially, and close to the median line and to its fellow of the opposite side; over it pass the fibres of the intermediary portion of the seventh nerve as they leave their nucleus. From the nucleus the fibres of the sixth nerve pass almost straight through the pons—some of the fibres passing between the bundles of the pyramidal tract—and emerge just below the pons. From this point the nerve passes along the cavernous sinus and enters the sphenoidal fissure, where it lies below the other nerves with only the ophthalmic vein below it—a point which is of importance in consideration of the clinical fact that there was no evidence at any time of congestion of the retinal veins. Remembering, then, the close promixity of both nucleus and nerve to other structures it will be seen that almost any gross lesion affecting either of them would almost certainly affect some other structure, either nervous or vascular; but here there was no evidence of any such implication. In this manner, then, one may practically exclude tuberculous and other meningitis, cerebral tumour, abscess, softening, or hæmorrhage, as well as other causes of ocular palsies, for it would be difficult to imagine that any one of these could act upon one point only—and that one so small—without giving rise to any symptoms other than those referable to that point, first on one side and then on the other. Regarding connexions above the nucleus, fibres from the cortex to the sixth nucleus probably cross in the pons, so that unless two lesions had occurred, one on each side, in the cerebral cortex or in the corona radiata, which is not probable, a lesion would have occurred in that most complicated junction, the pons, without giving rise to any but isolated symptoms of an evanescent character, which would be difficult to imagine possible.

No functional disturbance was found which, acting reflexly, might for a time inhibit the activity of the nuclei of the sixth nerves. Hence, in spite of the facts that the patient was of quiet manner, and that, as Charcot and others have said, hysterical affections of facial and ocular muscles are very unusual, this case came to be looked upon as one of hysterical origin, and unless the future history of the patient brings to light further facts or manifestations, it is probable that in that convenient receptacle for unaccountable cases, hysteria, it will remain until further investigation throws new light upon the etiology and pathology of temporary paralysis of the ocular muscles.

ICE-CREAMS AT CARDIFF.—Before the stipendiary magistrate at Cardiff on July 6th an Italian was summoned at the instance of the sanitary authority for having neglected to keep his premises used as a common lodging-house in a clean and fit condition. The sanitary inspector stated that the houses were in a filthy condition, the yard was covered with animal refuse, and yet a number of organ-grinders and ice-cream vendors lodged there. The medical officer of health also described the dirty condition of the place in which ice-cream was made. The magistrate was satisfied that the yard was unfit for the manufacture of any article of human food, and fined the defendant £5 and costs, or one month's imprisonment.

NOTES ON THREE CASES OF EMPYEMA OF THE MAXILLARY ANTRUM IN WHICH A "BAD SMELL IN THE NOSE" WAS THE ONLY SYMPTOM COMPLAINED OF.

BY ADOLPH BRONNER, M.D., M.R.C.S.,
SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL; LARYNGOLOGIST TO THE BRADFORD INFIRMARY.

DURING the recent epidemics of influenza one of the common symptoms was severe catarrh of the nares, often of a purulent or muco-purulent nature. In many cases one or more of the accessory cavities of the nose became affected—the maxillary antrum, the sphenoidal or the ethmoidal cells, most frequently the former. Very few text-books deal at all fully with the diseases of the sphenoidal or ethmoidal cells, and the descriptions of disease of the maxillary antrum are most misleading and exaggerated. We read of exophthalmos, severe pains in the cheek, extensive swelling, copious discharge of offensive pus, &c. These symptoms certainly do occur in acute or severe cases, but in the large majority of cases the symptoms are not at all well marked. Often the patient complains only of a slight offensive discharge from one side of the nares, and frequently the only subjective symptom is a bad smell in the nose. In the three cases which I am recording the patients complained of nothing else except an occasional bad smell in the nose, which was frequently most offensive and disagreeable. Nor were there any marked changes to be found in the nares except slight hypertrophy of the mucous membrane.

CASE 1.—A woman, aged thirty-five years, single, had a severe attack of influenza three years ago, accompanied by muco-purulent rhinitis. Since that time she had noticed an occasional and sickly smell in the right nostril, which varied in frequency and intensity. It was often so offensive that the patient felt sick and miserable. When I saw her in February, 1896, the right nostril was apparently normal, with the exception of some thickening of the mucous membrane. Trans-illumination gave negative results (as in most cases). An exploratory puncture of the antrum was refused, as the patient said that "she did not wish to be experimented on." In July under chloroform I opened up the antrum through the alveolar process. A few drops of offensive pus escaped. A gold pin was attached to the false teeth, which the patient was wearing, and passed into the antrum. This was syringed out daily, and insufflations of aristol and boric acid were used. The smell disappeared after the operation and has not returned.

CASE 2.—A young woman was sent to me in April, 1897, for "polypi in the right nostril" and an offensive smell in the nose. Eight years previously the patient had all the upper teeth removed because they were loose and painful. Six years ago she first noticed an occasional and offensive smell in the right nostril, which had increased in severity and frequency. There was some hypertrophy of the mucous membrane of the right nostril, but no polypi. I passed a Lichtwitz exploratory trocar through the wall of the lower nasal meatus into the antrum and injected warm boric acid lotion. A large quantity of offensive pus came away through the right nostril, and the patient at once exclaimed, "That is the smell I complain of." The antrum was opened through the alveolar process and treated by insufflations, and recovery followed.

CASE 3.—A married woman, aged sixty-three years, had complained of an occasional and offensive smell in the nose and throat for several years. In the middle meatus of the right nostril there was a pulsating reflex, and on one occasion I could find a little pus in the middle meatus. In May, 1897, I passed a Lichtwitz trocar through the lower nasal meatus into the antrum and injected warm boric acid lotion. A little offensive pus came away; there was no return of the smell until June 4th. On June 10th, under cocaine, I opened up the antrum through the alveolar process. Up to the present there has been no return of the smell.

These three cases seem to prove that empyema of the maxillary antrum often exists without any of the alarming symptoms which are described in text-books. As a matter of fact, cases of disease of the antrum are fairly common, but are in most cases overlooked. I have purposely not entered into the details of the operation or the etiology of empyema of the maxillary antrum. The less severe cases are most frequently due to disease of the mucous membrane of the nares. I have also avoided entering into the details of differential diagnosis between the diseases of the maxillary antrum and those of the sphenoidal or ethmoidal cells. The symptoms are in many cases very similar.

Bradford.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

AN UNUSUAL INCIDENT IN LITHOTRITY.

BY SINCLAIR WHITE, M.D. R.U.I., F.R.C.S. ENG.

A MAN, aged fifty-two years, was admitted to the Sheffield Royal Hospital on June 21st last for the removal of a vesical calculus of many years' standing. Two days later I proceeded to crush it, but after working for a few minutes the lithotrite jammed with the blades three-fourths of an inch apart. A surgical instrument maker was sent for, but he was unable to liberate the blades, which were, of course, much too far apart to allow of the instrument being withdrawn. The only way of escape from the dilemma appeared to be in performing supra-pubic lithotomy. This was accordingly done, and after removing the stone we succeeded in protruding the blades of the lithotrite through the wound. They were then placed in a vice and pressed together until the female blade fractured. The male blade could now be driven home and the instrument was removed. Had the vice failed us we were prepared to file through the projecting end of the male blade. Owing to the lithotrite being in the urethra the bladder could not be distended; but by using a large rectal bag no difficulty was experienced in reaching the bladder.

The stone, with the crushed débris, weighed one and a half ounces, and was a typical oxalate of lime calculus. The lithotrite was an old one which had seen much service. The patient is doing well.

Sheffield.

NOTE ON A CASE OF RUPTURED DUODENUM; DEATH IN SIXTEEN HOURS.

BY NAPIER CLOSE, L.R.C.P. EDIN., &c.,
LATE HER MAJESTY'S CONVICT SERVICE.

ON June 24th last I was called in the evening to see a boy, thirteen years of age, who had been kicked by a horse early in the morning of the same day. I first saw him twelve hours after the infliction of the injury, when his condition was as follows. He was lying in bed upon his back with the hip-joints slightly flexed. His face was pale and wore an anxious expression. He complained of some pain in the lower part of the abdomen, which was slightly distended and very tender. There was no visible bruise or external wound. The abdominal muscles were rigidly contracted, which fact, combined with the tenderness, prevented the acquirement of any information from palpation. The percussion note was quite dull over the whole of the lower part of the abdomen and in the left flank. There was a band of tympanitic resonance below the costal margin and ensiform cartilage, and in the right flank also the note was tympanitic in character. The temperature in the mouth was 102·5°F. The pulse was 140 to the minute, rather small, but not thready. He was quite conscious, and gave me a connected account of the accident. The boy's father, who saw him immediately after the accident, told me that he was soon able to walk some distance up the field in which it had occurred, and then he lay down for some time. Subsequently he was taken home, and after the application of hot flannels he so far recovered that he was able to get about for some hours, and walked upstairs and downstairs. Towards evening he vomited, and I was sent for. Dr. Crosby, of Leicester, who was staying with me, kindly saw the patient, and we passed a catheter, drawing off clear urine without blood. From the symptoms

Digitized by Google

and examination we concluded that the boy had in all probability sustained a rupture of the intestine, and that in immediate laparotomy lay his sole chance of life. Accordingly I asked Dr. Balfour, of Chard, to administer chloroform. Before Dr. Balfour's arrival the boy rapidly got worse; the pulse at the wrist became imperceptible, and the temperature fell to 97°. The lad was evidently dying, and under the circumstances it seemed useless to risk the accusation of having killed him. He died about an hour afterwards. Dr. Crosby told me that before death the abdomen became much more distended, with tympanitic percussion note all over, and loss of liver dulness.

By the coroner's order I made a post-mortem examination fourteen hours after death. The peritoneum contained about two pints of cloudy fluid, mixed with partially digested food. There were flakes of recent lymph adherent to the intestines, which were much reddened. On turning back the omentum and coils of small intestine a rent in the second part of the duodenum was revealed, from which the chyme was escaping. It was large enough to admit four fingers, and was distant four and a half inches from the pyloric orifice.

The case seems to me to be of interest from the fact that, notwithstanding the presence of such an extensive lesion in the abdomen, the boy was able to get about for several hours, and apparently suffered little pain. It was, in fact, difficult at first to persuade his parents that he was in imminent danger of death.

Chard.

NOTE ON A CASE OF PUERPERAL ECLAMPSIA.

By JOSEPH JOHN STACK, L.R.C.P. EDIN., L.R.C.S. IREL.

A MARRIED woman expected to be confined of her first child in the first week of September, 1896. During the early part of her pregnancy, which was wholly spent on board ship, she enjoyed the best of health, and was evidently looking forward with pleasurable anxiety to her approaching maternity. On reaching England, however, she seemed very much upset by hearing that her husband would shortly be out of employment. On the night of the bad news she was considerably alarmed at the fact that her ankles were much swollen, and that her boots seemed to be too small for her feet. This happened about the end of June. On July 3rd she consulted me about the condition of her legs, and at my request she sent me a sample of her urine, which was passed scantily, and which upon examination was found to contain albumin to about one-twelfth of the specimen in the test-tube. For a few days after her visit I attended her and strongly advised her not to undertake the long journey to Ireland which she then contemplated for her accouchement. After some days' rest in bed the swelling in the legs more or less disappeared, but the albumin was still present in the urine. She was now affected with an irritable cough; the arms and hands began to swell, as also did her face. She complained of a severe pain over the left half of her head. On the night of July 16th she had a severe attack of diarrhœa and vomiting, and on the following morning she was unable to remain in one position. She was now seized with convulsions, which continued off and on during the day, with only the intervention of the profound coma that succeeded each attack. All available classical medicaments were tried—chloroform was inhaled and chloral in twenty-grain doses was administered per rectum every two hours; but as the fits got more prolonged and the intervals between them began to decrease I, with the approval of a medical friend (Mr. H. J. Dixon), proceeded to bring on labour. This procedure was attended with considerable difficulty and anxiety. A uterine sound was first introduced so as to separate the membranes, and after some waiting I was able to introduce my finger-tip so as to feel the presenting head of the child, when I succeeded in puncturing the membranes with a hairpin straightened out. For some time after this there was an abatement in the symptoms; the fits did not cease, but they were not so frequent. The pains of labour now came on, and with each pain a fresh seizure took place. The patient was kept under chloroform as much as seemed consistent with her safety, but the only course that seemed clear to me was to empty the uterus with all possible speed. I dilated the os uteri with my fingers, and after unsuccessfully attempting to introduce the forceps I turned and delivered her of a living male infant. She had a slight convulsion after delivery. For some days afterwards the patient was in a rather low condition; the pulse was about 120 and the temperature ranged between 100° and 103° F. She was frequently syringed out with lysol, and iodoform was copiously dusted on the vulva. A little trouble with her breasts, which lasted for a week or so, caused her to lose her spirits; but she eventually made a good recovery, and only regretted the loss of her infant. The urine was quite free from albumin two days after delivery.

I know that dilatation of the os and turning are both strongly deprecated by many of the leading lights of the profession; but under the circumstances I felt that I was obliged to have recourse to both measures. Stimulants, nutriments, quinine, and occasional douching were continued until convalescence.

ST. GEORGE'S HOSPITAL.

A CASE OF ACUTE YELLOW ATROPHY OF THE LIVER IN A GIRL TWELVE YEARS OLD; NECROPSY.

(Under the care of Dr. CAVAFY.)

ACUTE yellow atrophy of the liver in many respects greatly resembles phosphorus poisoning; in fact, so great is the likeness that Munk, Wagner,[1] and others have maintained that all cases of acute yellow atrophy are due to poisoning by phosphorus. It is said that the absence of leucin and tyrosin from the urine is against a diagnosis of acute yellow atrophy and in favour of phosphorus poisoning. The history of the following case is by no means unlike a case of sub-acute poisoning by phosphorus. Apparently no bacteriological examination was made; this would have been of great interest in view of the theory held by many that the disease is bacterial in origin. For the notes of the case we are indebted to Dr. E. T. Fison.

A girl, aged twelve years, was admitted into St. George's Hospital on March 10th, 1897. Three weeks previously she had complained of having general pains, which lasted three days; these were followed by what was thought to be a "bilious" attack, as shown by vomiting after food and headache. Since March 3rd she had been jaundiced. There was no history of fright or mental shock. When admitted the child was very jaundiced and looked ill. The temperature was 101·4° F., and the pulse was 92. The tongue was coated. There was much bile in the urine, but none in the fæces. Physical examination showed that the heart and lungs were normal, but the liver appeared to be enlarged and extended to three fingers' breadths below the costal margin. The child complained of persistent pain in the right hypochondrium, and was occasionally sick; her appetite was bad. The jaundice varied greatly in its intensity from day to day. The case seemed to be rather different from one of simple or catarrhal jaundice on account of the raised temperature and the enlargement of the liver; however, a provisional diagnosis of simple jaundice was made. By March 15th the temperature had reached normal, but the symptoms and jaundice remained the same. On the 20th the liver appeared to be smaller, but the general condition was unaltered. On the 21st, at midday she suddenly became drowsy, she would not perform any action or answer questions, and she was unable to swallow. The reflexes were not abolished, but urine and fæces were passed into the bed. The temperature was slightly above the normal; there was no delirium. On the 22nd she remained in the same state, the liver appeared

[1] Archiv der Heilkunde, 1832, p. 364.

Digitized by Google

to be slightly smaller, but there was some uncertainty about this. On the 23rd in the morning hæmorrhages were noticed over the sacrum; in the evening she had an attack of convulsions of the arms followed by rigidity; the temperature was now 102° and the pulse was 160; the tongue was dry and brown. The patient was completely comatose and died at midnight on the 23rd, sixty hours after the onset of acute symptoms. No leucin or tyrosin was found in the urine; the urine examined was not concentrated.

Necropsy.—Dr. Arthur Latham made a post-mortem examination thirteen hours after death. The body was rather wasted, the skin and conjunctiva were stained light yellow, and in the skin there were a few scattered petechial hæmorrhages. Rigor mortis was marked. There was no fluid in the pleural cavities. The right lung weighed 8 oz. and the left was the same weight, and showed a few sub-pleural petechial hæmorrhages. Both lungs were very œdematous, and there was muco-pus in the larger bronchi. The larynx and trachea, the bronchial glands, and the thyroid were all normal. The heart weighed 1½ oz., the cardiac muscle was bile-stained, and the pericardial fluid was bile-stained. The valves were good. There was a considerable quantity of bile-stained fluid in the peritoneal cavity; numerous sub-peritoneal hæmorrhages were present, especially along the greater curvature of the stomach and in the great omentum. The liver weighed 3 lb. 8 oz. and was flabby; the capsule was somewhat wrinkled, especially on the under surface of the right lobe. The organ was not larger than usual, but was displaced slightly downwards. On section the substance was distinctly firm, of a light yellow-ochre tint, but with no red areas, although there were a few minute hæmorrhagic patches. The lobules were indistinctly outlined. The gall-bladder was full of green bile mixed with an excess of mucus. The ducts were normal and there was no obstruction in them, but at the papillary orifice in the duodenum there were some slight inflammation and œdema which prevented the ready expression of the bile. The portal vein was normal. The glands in the portal fissure were slightly enlarged. On microscopic section very few natural liver cells were seen, and they were full of granules. The liver tissue was to a great extent replaced by granular and fatty débris contained in a reticulated, homogeneous, nucleated structure, the nuclei probably being derived from liver cells. There was no leucin or tyrosin observed. The capsule of the liver was slightly thickened; the pancreas was normal; the spleen was very congested and rather soft; the kidneys weighed 3½ oz. each; the cortex was pale; and the adrenals were normal. The stomach contained altered blood. There were patches of submucous hæmorrhages. In the intestines was a large number of submucous hæmorrhages, especially in the cæcal region. The rectum was normal. The bladder was normal. The muscle of the uterus was bile-stained. The brain weighed 3 lb. 2 oz.; the dura mater was bile-stained, and the brain tissue was normal.

Remarks by Dr. FISON.—The diagnosis of the case appeared to rest between cholæmia, biliary cirrhosis, and acute yellow atrophy of the liver. The necropsy showed that the liver was in a condition of acute atrophy. The chief points of interest seem to be the age of the patient, the fact that the acute atrophy was preceded by a temporary enlargement of the liver, and the difficulty in the diagnosis. If there had been any certainty about the apparent diminution in the size of the liver the diagnosis would have presented no great difficulty; there was, however, considerable doubt about this. On referring to the literature of this disease Osler states that the disease is most common between the ages of twenty and thirty years, but is occasionally seen in young children. In St. Bartholomew's Hospital Reports Mr. Freeborn of Oxford and Dr. West[2] report three cases, all occurring in children—two boys aged four and seven years and one girl aged four years. There was no difference in the symptoms from cases of acute yellow atrophy in adults. All of them died within forty-eight hours of the onset of cerebral symptoms, and in two of the cases the liver was temporarily enlarged previously to the atrophy. Moxon[3] noted the same thing in the case of a woman, aged thirty-four years, who died from acute liver atrophy. Merkel[4] also reports a case of a child, six years old, who suffered at first from malaise and loss of appetite and jaundice. Eight days from the commencement of the illness the liver was diminished, the jaundice increased, convulsions came on, and death occurred on the seventeenth day. The temperature was not raised. Greves[5] has collected seventeen cases, all of which occurred in children under ten years old, the youngest being an infant aged three months. Yeoman[6] records a case of acute yellow atrophy in a female child aged ten months. Death occurred on the third day after jaundice was first noticed. F. Lanz[7] reports a case in a boy four years old. Death followed four days after the development of the first symptom. The above cases show that jaundice occurring in children does not invariably lead to a favourable result, and that it is well to bear in mind the rare occurrence of acute yellow atrophy of the liver.

STANLEY HOSPITAL, LIVERPOOL.

A CASE OF URÆMIC ECLAMPSIA IN THE SEVENTH MONTH OF PREGNANCY; INHALATIONS OF OXYGEN; RECOVERY.

(Under the care of Dr. C. J. MACALISTER.)

ASPHYXIA is the immediate cause of death in some cases of puerperal convulsions, and for these Dr. Macalister's treatment by oxygen will probably prove very beneficial; unfortunately, the fatal issue in but few cases is the result of respiratory difficulty, and therefore the method can never have a very wide application. Pilocarpine, though in many cases of great value, is decidedly harmful in others.[8] For the notes of the case we are indebted to Mr. F. Deas, house surgeon.

A woman, aged thirty-one years, was admitted to the Stanley Hospital, Liverpool, late on Jan. 20th, 1896, under the care of Dr. Macalister. On admission the patient was absolutely comatose. A note sent with her by her medical attendant stated that she had only been taken ill that morning, that he had seen her in one fit, that she had passed no urine since the previous day, and that she was seven months pregnant. Her husband stated that she had enjoyed the best of health up to the evening of the 19th, when she complained of headache and of feeling very drowsy. She was pregnant for the first time. Immediately after the patient was put to bed she had a rapid series of violent convulsions, the face became extremely livid, the breathing was stertorous, and at times of the Cheyne-Stokes character. The fit lasted about half an hour. The convulsions gradually subsided, and the patient again passed into a deep coma. No urine or fæces were passed during the fit. While still comatose a catheter was passed, and two ounces of urine were drawn off, which on boiling became nearly solid with albumin. In about a quarter of an hour the patient had another violent convulsive seizure, the lividity and difficulty of breathing being very severe. Immediately after the commencement of the fit the inhalation of oxygen was commenced, and with very marked effect. Although the convulsive movements continued they were much less violent, the breathing soon became quiet, and in a very short time, about a minute, the lividity had quite disappeared. The movements ceased in about fifteen minutes, and she again passed into a comatose condition. During the night the patient had four attacks, each lasting from ten to fifteen minutes, and in each attack oxygen was administered with equally good effect. In the intervals between the fits she was quite comatose. Early on the morning of the 21st she gave birth, unconsciously, to a dead seven months' fœtus. On the 21st she had five attacks, each lasting about ten minutes. She was still comatose in the intervals, and could not be roused sufficiently to take anything by the mouth. Urine had to be drawn off, being still loaded with albumin. An enema was administered, which brought away a copious stool. On the 22nd she remained much in the same condition. She had four convulsive attacks, each lasting about ten minutes. She passed a small quantity of urine in one fit. On the 23rd she was conscious for the first time, although very drowsy. The bowels acted well after an enema of sulphate of magnesia. She had three attacks of convulsions, each lasting from ten to fifteen minutes, but they were not so violent as the previous attacks had been. On the 24th, and again on the 25th, she had two seizures, each of which was

Digitized by Google

milder than the previous one. In all these attacks the dyspnœa and lividity were extreme, but in each case these urgent symptoms were promptly relieved by the inhalation of oxygen, which also appeared to have a decided effect in abating the violence of the convulsions. Up to this time (the 25th) she had not voluntarily passed more than about ten ounces of urine, although from thirty to forty ounces were drawn off by the catheter. The urine contained large quantities of albumin, as much as five-sixths. Retinal hæmorrhages were to be seen in both eyes. On the 26th the patient was much better. She began to pass urine naturally (forty ounces during the day), and the albumin was reduced to two-thirds. From this date she made an uninterrupted recovery and was discharged on March 12th. When she left the hospital there was the merest trace of albumin in the urine and the retinal hæmorrhages had to a great extent cleared up. The patient was seen quite recently. She had not had any bad symptom since leaving the hospital. She was delivered about the middle of May, 1897, at full term, of a dead child. Her medical attendant stated that the labour was easy, and that there had been no sign of any recurrence of last year's trouble.

Remarks by Mr. DEAS.—In view of the high mortality in cases of uræmic eclampsia in pregnancy the above case may be of interest, especially as showing a use for oxygen previously recorded by Dr. Macalister in THE LANCET of Dec. 7th, 1895. There are several points of interest in the case, the chief, I think, being the markedly beneficial effect of the oxygen. It was the extreme lividity and dyspnœa which led to its use. It was evident that, whatever the toxin might be, the patient's most urgent need was to get her blood re-oxygenated, and it occurred to me to introduce free oxygen as directly as possible. It certainly seemed far safer than restraining the violent convulsions by means of chloroform in a patient alternating from convulsions to deep coma, the coma being also a great hindrance to exhibiting any purgative or diaphoretic drugs by the mouth. Two other points struck me forcibly at the time. Twice I administered hypodermically one-third of a grain of pilocarpine nitrate, and each time it was followed immediately by a violent convulsive seizure and vomiting. The other point was the excitation of the convulsions by slight peripheral irritation, eight attacks following immediately the passage of the catheter, and four after a vaginal douche.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Two Unusual Cases of Tubal Gestation.—Primary Sarcoma of the Body of the Uterus.—Exhibition of Specimens.

A MEETING of this society was held on July 7th, Dr. WILLIAM DUNCAN, Vice-President, being in the chair.

Dr. ARTHUR GILES and Dr. EWEN MACLEAN contributed a paper on Two Unusual Cases of Tubal Gestation, the one causing chronic intestinal obstruction and associated with hæmato-salpinx of the non-gravid tube, and the other simulating retroversion of the gravid uterus. Case 1.—The symptoms and physical signs were principally those of pelvic cellulitis, together with evidences of pregnancy, whilst the case was complicated by chronic intestinal obstruction. In some respects the conditions suggested retroversion of the gravid uterus, and with this idea an attempt was made to push up the mass lying behind the cervix under an anæsthetic, but without success. The patient gradually got worse, and the propriety of opening the abdomen was discussed, but it was agreed that the patient's condition was so grave that she would probably not stand the shock of operation—an opinion confirmed by her death shortly afterwards. Case 2.—The symptoms and physical signs were those of retroversion of the gravid uterus causing retention of urine. An attempt to push up the mass behind the cervix under an anæsthetic was unsuccessful. But while the patient was resting in bed the symptoms improved. Nine weeks after admission she was operated upon and a tubal gestation was found, filling up the pelvis behind the uterus. Two conclusions were drawn as to treatment. First, that a pelvic tumour which differed in signs and symptoms from classical types should not be treated by the expectant method, but should be dealt with surgically as soon as possible. Secondly, that if a tubal gestation be diagnosed before rupture takes place the possible train of disasters will be best averted by immediate operation.—Dr. HORROCKS considered that it would have been better to have operated on the case which afterwards proved fatal. No doubt it was a difficult point to decide, but he considered it a good rule that when in doubt it was better to operate. This rule was, indeed, more firmly established now that better weapons were available, such as saline injections to deal with collapse, and also a more perfect system of asepsis. He asked what was the cause of death. Was it hæmorrhage? And, if not, was there any clotting or embolism? He also pointed out that the uterus was only three inches long; obviously from the size of the fœtus the uterus had either not increased in size as was usual or the fœtus had died and involution to some extent had taken place.—Dr. DRUMMOND ROBINSON asked Dr. Giles and Dr. Maclean why they had considered that the case might possibly have been one of cellulitis. He thought that the physical characters present suggested peritonitis rather than cellulitis. He also drew attention to the fact that a history of injury was absent—a point against the diagnosis of cellulitis.—Dr. MAIDLOW remarked that the history of the physical signs pointed to pelvic peritonitis and not cellulitis—a fact which, with the signs of pregnancy, he thought might have pointed to ectopic gestation. Moreover, symptoms of intestinal obstruction of any severity were in his experience very rarely associated with retroversion of the gravid uterus.—After some remarks by Dr. GALABIN, Dr. GILES, in replying, said that he quite agreed with Dr. Horrocks's rule, "when in doubt operate." In the first case, however, the patient's condition was so bad that it seemed impossible that she could stand an operation. The cause of death was intestinal obstruction and collapse. His reason for regarding the case as one of pelvic cellulitis rather than peritonitis was that in the first place there was at the time no reason to suppose that the appendages were affected, and he was in the habit of associating pelvic peritonitis with tubal mischief. In the second place the board-like hardness was more suggestive of cellulitis than peritonitis.

Dr. LEWERS read a paper on a case of Primary Sarcoma of the Body of the Uterus (Deciduoma Malignum) in a patient, twenty-four years of age, treated by vaginal hysterectomy. The patient had been married a year and believed that she had had three miscarriages, at two months, six weeks, and three weeks respectively. She came under observation on account of persistent metrorrhagia, dating from the time of the first supposed miscarriage, about eight months previously. The case on admission was at first supposed to be one of incomplete abortion, but after dilatation of the cervix examination showed that the symptoms were due to a malignant growth in the body of the uterus. Vaginal hysterectomy was performed on Feb. 11th, 1897; the patient recovered and was free from any sign of recurrence in May last. An examination of sections of the growth showed it to be a sarcoma and essentially identical with what had been described under the name of deciduoma malignum. Dr. Lewers examined the evidence as to the patient having ever been pregnant at all. While admitting the impossibility of proving she had never been pregnant, he considered that, having special regard to the fact that menstruation had never been regular, there was some probability that conception had never occurred.—Dr. EDEN said that the question of the connexion of these growths with pregnancy was the point upon which the whole theory of deciduoma malignum was established. If it could be shown that the disease had occurred in women who had never conceived then the theory must be abandoned, but nothing could be more difficult than the absolute exclusion of pregnancy by scientific proof in any woman, and in women whose menstruation was irregular it became quite impossible. It was obviously unfair, however, to agree that every woman might be assumed to have been pregnant unless the contrary could be proved. Direct evidence of pregnancy being so much more easily obtained, they were justified in asking that in those cases the positive evidence of pregnancy should be conclusive. In Dr. Lewers's case he thought there could be no reasonable doubt that the woman had never been pregnant at all, although in the nature of things absolute proof of this was impossible. Two other cases of deciduoma malignum had been recorded

Digitized by Google

in which the evidence of pregnancy was equally wanting. It could not be too strongly emphasised that irregular hæmorrhages occurring in women who were the subjects of malignant disease of the uterus were no proof of abortion.

The following specimens were exhibited:—

Dr. LEWERS: Primary Sarcoma of the Body of the Uterus (to illustrate his paper).

Dr. GALABIN: An Œdematous Fibroid, weighing 20lb., removed by Hysterectomy.

Dr. GILES: Molluscum Fibrosum from the Labium Majus of a pregnant woman.

BRITISH GYNÆCOLOGICAL SOCIETY.

Mechanism of Inversion of the Uterus.—Escharotics in the Treatment of Uterine Cervical Cancer.

A MEETING of this society was held on July 8th, Mr. MAYO ROBSON, President, being in the chair.

Professor HECTOR TREUB, of Amsterdam, read a paper on the Mechanism of Inversion of the Uterus. He related a case of inversion in a patient who had been pregnant three times. Each pregnancy had ended in abortion, the last occurring seven years ago. For some time she had observed that something was protruding in the vulva, but she could always reduce it easily. Eleven weeks ago a prolapse appeared suddenly and could not be reduced. This caused much pain, and brought about hæmorrhage to the extent of making her swoon. Her general health had deteriorated, she had lost a fluid in appearance like meat-juice, and had been feverish. On examination a total inversion of the uterus, including the cervix, was found. Hysterectomy was performed, and the patient made a good recovery. Besides the œdematous mucous membrane the uterus only showed a very small intra-mural fibroid near the fundus. Microscopical examination showed that the muscular tissue was in a normal condition and that there was no question of atrophy of the uterine wall. Professor Treub proceeded to discuss the views held as to the mechanism of inversion. In only one group of cases was the mechanism wholly understood—viz., in those following immediately after labour; then the two elements upon which, according to Gaillard Thomas, the inversion depended were present—viz., relaxation and inertia of the uterine walls and downward traction or pressure. In other cases the explanation was far less obvious. Professor Treub rejected the theories of Küstner and of Schanta and Gottschalk as insufficient and submitted the following theory: "The base of a sessile tumour cannot contract because of the implantation of the tumour, which diminishes or altogether abolishes the contractility of that part of the wall. And it cannot be that only the contractility of that base is diminished; the surrounding parts must necessarily be feebler within a greater or smaller circumference. If from the outset the tumour is intra-mural the smaller degree of resistance of that part of the uterine wall, coupled with intra-abdominal pressure, may occasionally bring about a slight beginning of inversion; and when this is the case the conditions are essentially the same for sessile and intra-mural tumours and for the partial inversion described by Rokitansky. A circle of uterine tissue is abruptly curved in the place where Rokitansky found the external indentation. I need hardly say that in that incurved circle the uterine muscle must be absolutely paralysed. And this paralysis again will not be confined to a linear circle, but gradually diminishing will extend over a greater or smaller surface. The contractions of the normal part of the uterine wall will try to expel the part of the wall that acts as a foreign body. These expulsive efforts may slightly increase the inversion as far as the paralysis surrounding the circle of inversion permits, thus displacing the circle itself and paralysing another part of the uterine wall. Necessarily the extension of the partial paralysis proceeds farther in the uterine wall, too, and by the repeated action of this muscular play the inversion may gradually become complete as regards the body of the uterus. As soon as the body is inverted there is no longer any excitement for uterine contractions, and the inversion of the cervix generally does not take place. And it is the intra-abdominal pressure, again, that may invert the cervix too."

Dr. PURCELL, Dr. HEYWOOD SMITH, and Mr. SKENE KEITH having spoken, Professor TREUB replied.

Dr. HERBERT SNOW read a paper on Escharotics in the Treatment of Uterine Cervical Cancer. Of the various caustics used two stood out pre-eminently—viz., chloride of zinc and potassa fusa. As caustics they were on a par, but whereas the pain induced by the former was difficult to relieve, the pain resulting from potassa fusa could be instantly checked by the application of water; hence Dr. Snow believed that "the ideal caustic for malignant disease of the uterus or elsewhere was potassa fusa." He thought treatment of the cancerous cervix by escharotics preferable to hysterectomy.—The PRESIDENT thought that some of them would not agree with Dr. Snow's conclusions with regard to hysterectomy, because they could point to cases where this operation had been performed, and where the patients had remained well for much longer than the three years considered necessary to establish a cure. He would like to hear further details of the mode of application of potassa fusa; he had always regarded it as an agent rather difficult to control on account of its deliquescent properties. — Mr. SKENE KEITH said that he had used potassa fusa a good deal and believed it was originally an old Edinburgh remedy. He had applied it through a large Fergusson's speculum, rubbing it in in the form of a stick held in a caustic-holder. To prevent it from unduly spreading he used pyroligneous acid.—Dr. PURCELL and Dr. HEYWOOD SMITH made some observations, and Dr. HERBERT SNOW replied.

Reviews and Notices of Books.

Human Embryology. By CHARLES SEDGWICK MINOT, Professor of Histology and Human Embryology, Harvard Medical School, Boston. With 463 Illustrations. New York: The Macmillan Company. London: Macmillan and Co., Limited. 1897. Pp. 815. Price 25*s*.

THIS well got up and richly illustrated work is the result, the author tells us, of ten years' labour and is without doubt the fullest and most complete account of the embryology of man that has hitherto appeared in the English language. The author is well known and has made many contributions to the subject of embryology on his own account. His work as a whole may be regarded as a continuation, with special application to man, of Balfour's "Comparative Embryology," embracing in a very creditable manner the chief points in the very numerous and important additions to our knowledge that have been made by many workers throughout almost all the countries of Europe, not only in the embryology of human, but in that of the lower vertebrata and of the invertebrata.

Dismissing details of anatomy as being readily accessible in text books, Professor Minot plunges at once into the histology of the uterus. He takes exception to the view frequently expressed that the muscular tissue of the uterus essentially represents a hypertrophied muscularis mucosæ, believing that a muscularis mucosæ is not a primary but a secondary formation, and that it need not be coexistent with a mucous membrane, in support of which he points to the fact that in various instances in the animal kingdom a mucous membrane may be found without such a muscular layer. He describes with much precision and in considerable detail the appearances presented by the virgin uterus at the close of menstruation, his observations being opposed in some points to the statements of Sir John Williams; then by natural transition he passes on to describe the histological characters of the decidua serotina, vera and reflexa, and the results he obtained from the examination of various uteri at different periods of pregnancy. He entertains no doubt that the large cells of the decidua are directly derived from the connective tissue cells of the mucosa, the areolæ seen in section belonging to the glands which are considerably distended and distorted, and these

Digitized by Google

he thinks are really the distended capillaries described by Sir William Turner. It is difficult to demonstrate the decidua reflexa after the fifth month, and preparations which Professor Minot possesses show that as early as two months the decidua reflexa is undergoing hyaline degeneration, that at three months the degeneration is considerably more advanced, and that by the sixth and seventh month the reflexa can no longer be found. The changes in the mucosa following parturition are very well given. We are still curiously ignorant of the cause or causes of the formation of the decidua either in menstruation or gestation, as well as of the cause of delivery, though in regard to the last-named event many suggestions have been made. Some of these are briefly given by Professor Minot in the following sentence: "Mauriceau sought the stimulus which excites the uterus to normal contractions at the full term in the uterus having reached the limit of its expansibility; Naegele in the irritation caused by the embryo acting like a foreign body in the uterus; Engelmann, at least partly, in the degeneration of the decidual cells; Harse and others in the accumulation of carbonic acid in the blood of the uterus." Perhaps answers to the question will be obtained hereafter by careful studies in comparative anatomy. In the section on the Genital Products minute descriptions of the spermatozoa and ova are given, in which most of the recent researches are embraced. Professor Minot strongly advocates the polarity of the ovum, the nucleus being excentric and the yelk grains accumulating at the opposite pole. The maturation of the ovum rendering it fit for impregnation is marked, as von Baer originally maintained, by the disappearance of the germinal vesicle, which loses its membrane, whilst the contents present the phenomena of karyokinesis; the polar bodies representing the larger portion of the nucleus are then extruded, whilst a small portion of the nucleus remains to form the female pronucleus. In regard to the rupture and subsequent changes that take place in the Graafian follicle, Professor Minot describes the coagulum which fills the follicle after the rupture as being rapidly penetrated by tissue which grows into it from the wall of the follicle, composed of spindle-shaped connective tissue cells and large cells containing lutein granules with bloodvessels. He agrees with Benckiser's statement that the lutein cells arise exclusively from the theca interna. Professor Minot refers to the experiments of Hertwig and Fol as being the first to show that a single spermatozoon suffices to fertilise a single ovum, and, in fact, that the first spermatozoon that wins the race "prevents the penetration of other spermatozoa. How, is undetermined." Hertwig, however, states very definitely that at the moment the seminal filament has bored its way into the egg a fine membrane detaches itself from the yelk over its whole surface, due probably to contraction of the egg plasma, causing the expression of nuclear fluid, which renders the penetration of another male element impossible. The concordant testimony of a multitude of observers supports Hertwig's views; still, the experiments of Newport should not be altogether overlooked, which were to the effect that ova attacked—we will not say impregnated—by many spermatozoa were more perfectly developed than when only one or two appeared (to him) to enter the ovum. A minute description is given of the segmentation of the ovum and of the formation and differentiation of the ectoderm and entoderm, which he considers should receive the distinctive appellation of the diaderm stage; and this is followed by an account of what he terms the "law of concrescence," though the term "process" might with advantage have been exchanged for "law." In regard to the further development of the embryo from the appearance of the medullary groove to the origin of the cardiac and uro-genital systems, we must refer the reader to the original for the numerous details which have been culled by the author from a very large number of works on Embryology; suffice it to say he has studied the bibliography of each stage very carefully, and whilst giving the views of each investigator he does not hesitate to impartially criticise and often to correct them from his own large experience. There is a valuable chapter on Known Human Ova of the Second and Third Weeks, in which Professor Minot has collated all the descriptions of embryos not over three weeks—a task that has not hitherto been attempted. He has been successful in discovering about thirty-eight cases, of which a few are rather doubtful. The fourth part is devoted to the consideration of the fœtal appendages, including the chorion, amnion and pro-amnion, yelk sac, allantois, and umbilical cord and the placenta. The last part is devoted to the growth and development of the fœtus, the several organs and systems being taken in order. The account of the Development of the Nervous System is particularly good and complete. Speaking of the differentiation of the cerebral hemispheres he remarks: "By a long-continued tradition it has become customary to describe the process as the sub-division of the primary vesicle into two secondary vesicles designated as the fore-brain proper (Vorderhirn, prosencephalon) and 'tween brain (Zwischenhirn, thalamencephalon). Such a description, however, seems to me hardly justified either by embryology or comparative anatomy, and to be especially apt to mislead and confuse." He proceeds to describe the hemispheres correctly as outgrowths of the primary vesicle.

Professor Minot has introduced a few, but very few, new terms, amongst which we may mention "ectental" ine, "diaderm," "concrescence," and "aniages," the latter term derived from the German and being equivalent to "rudiment." The text is illustrated by a great number of woodcuts, some of which are reproductions of those contained in other, and for the most part original, treatises, whilst others, and the larger number, are from preparations in the author's own collection. The treatise may be strongly recommended as an excellent exposition of the present state of embryological knowledge.

JOURNALS, REVIEWS, &c.

Guy's Hospital Gazette.—A special number of this Gazette dated June 7th has been issued with the twofold object of recording the events connected with the opening of the new medical school buildings, and of drawing attention to the advantages offered by this school to intending students. The article on the New School is illustrated.

The London Hospital Gazette.—The issue of this Gazette for June is perhaps one of the best that has yet left the hands of the editors. The opening article, "Esprit de Corps," contains some sound advice, and the humorous contributions are good, from that of the woman who "'ad digestion of the lungs and amenia" to the note concerning clerks and dressers, which among other advice advocates the good plan that the clerk or dresser who arrives earliest should fill in the names of his colleagues in the attendance book, as custom speaks favourably of the system. Medical students who are cyclists will heartily enjoy the article on the Surgery of the Pneumatic Tyre, wherein are set forth the appropriate treatment for punctures and the symptoms which suggest operation.

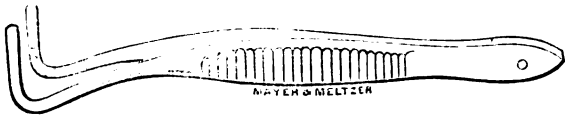
The St. Thomas's Hospital Gazette for June is more serious in its matter, but will be universally appreciated by students of the Hospital. There is an illustrated description of the new athletic ground at Chiswick, "the promised land which so many generations of students have hoped for and departed without seeing," which has now been entered into. Dr. T. D.

Digitized by Google

Acland concludes his interesting paper on Compulsory Vaccination.

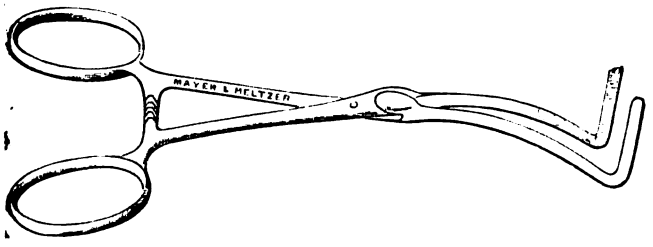
St. Bartholomew's Hospital Journal, like the foregoing, presents to its students rather solid fare. The subject of headaches is treated by Dr. Gee, and Tropical Diseases is the topic discoursed upon by Dr. W. H. Maidlow in his second contribution concerning the Ship's Surgeon and some Tropical Diseases. Mr. H. J. Walton, in A Plague-Wallah, incidentally mentions that the purdah, though designed with the object of concealing the loveliness of maidens who might otherwise be the object of evil design by the "Kafir," often leads the fair ones into trouble, as, thanks to the extremely limited range of vision which the eye-holes afford, the ladies are constantly falling between the railway carriages and the platforms. There is also a report of the paper read before the Abernethian Society by Dr. James Morrison on the Treatment of the Puerperal Uterus.

HOLIDAY PUBLICATIONS.



The London, Chatham, and Dover Railway Company's *Guide to Paris* presented gratis by the company will be found a most useful little companion for a visitor to Paris. The sectional street plans are on a large scale and very clearly printed. It also contains a useful list of the sights to be seen, prices of public conveyances, &c.

Summer Holidays in North-East England. London: Walter Scott, Ltd. Price 1*s*. 6*d*.—This is really a series of photographic illustrations of picturesque places in North-eastern England with short descriptive letterpress. There is certainly a comparatively unexplored field of beauty in this region, and intending holiday makers cannot do better than consult the pages of this book.



New Inventions.

NEW PALPEBRAL FORCEPS.

THESE forceps are made in two varieties, one with bow handles and step-catch fixation, furnished with the antiseptic joint; the other like the ordinary spring forceps. The blades are slightly curved backwards in their course and

finish by being bent forwards at a right angle. At this angular portion, which is about one inch in length, they are slightly roughened on their inner surfaces to prevent slipping,

and are so made that, closing in a parallel manner, they give an equal grip throughout this area. These instruments have been found useful as fixation forceps in various operations upon the lids, such as the removal of Meibomian cysts, plastic operations, &c. They are made by Messrs. Mayer and Meltzer, Great Portland-street, W.

Harley-street, W. H. WORK DODD, F.R.C.S. Eng.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY MEETING of the Council was held on July 8th, the President, Sir WILLIAM MACCORMAC, Bart., being in the chair.

The PRESIDENT reported the result of the meeting for the election of members of the Council, as recorded in THE LANCET of July 3rd, and he further stated that Mr. Watson Cheyne and Dr. Ward Cousins, being fourth and fifth on the list of the successful candidates, would be the substitute members of Council for the late Mr. Oliver Pemberton and the late Mr. Walter Rivington respectively.

Mr. Howse, Dr. Ward Cousins, Mr. Owen, Mr. Godlee, and Mr. Watson Cheyne were introduced, and made a declaration in the terms of the oath prescribed by the Charter of 1800, and took their seats as members of the Council. A vote of congratulation to the President and to Sir Thomas Smith on their receiving the honour of a baronetcy was passed.

The President reported the proceedings of the half-yearly meeting of Fellows on July 1st, as already published in THE LANCET of July 10th.

The Council proceeded to consider what reply should be sent to the memorial in reference to medical aid associations from Fellows and Members of the College practising in and about Plymouth, Devonport, and Stonehouse. It was resolved: "That the memorialists be informed that the Council are of opinion that the disciplinary powers provided by Section XVI. of the by-laws do not entitle them to question the legality of Fellows and Members of the College holding the appointment of medical officer to medical aid associations such as those referred to in the memorial, and the Council cannot therefore endorse the refusal of any Fellow or Member of the College to meet in consultation (particularly in urgent cases) registered practitioners when acting in conformity with their legal rights." It was also resolved that similar replies should be sent to the Norwich Medico-Chirurgical Society and to the Beckenham and Penge Medical Society.

The Council having learned that a medical man had falsely described himself as a Member of the College resolved to instruct their solicitor to institute legal proceedings against him.

A letter dated July 5th was read from Dr. R. R. Rentoul enclosing for the consideration of the Council a copy of his draft Bill for the Registration of Midwifery and other Nurses. The draft Bill was referred to the President and Vice-Presidents for consideration.

A letter was read from Sir William MacCormac stating that in anticipation of the expiration on August 1st next of his period of office on the Court of Examiners, he desired to place his resignation in the hands of the Council to take effect from the end of the Pass Examination for the Membership to be held this month, and that he was not a candidate for re-election. This vacancy, and that resulting from Mr. Davies-Colley's resignation, will be filled up at the next ordinary meeting of the Council.

The following professors and lecturers were elected for the ensuing year:—Hunterian Professorships: Henry Morris (The Surgery of the Kidney), Frederick Gymer Parsons (The Muscles of Mammals), and Charles Stewart. Arris and Gale Lectureship: Thomas Grigor Brodie (The Place of Formation and Chemical Properties of the Antitoxins). Erasmus Wilson Lectureship: Holburt Jacob Waring (The Pathology and Treatment of those Diseases of the Liver which are amenable to direct Surgical Interference).

Sir William MacCormac was unanimously re-elected President, and Mr. Alfred Willett and Mr. H. G. Howse were appointed Vice-Presidents.

The next meeting of the Council will be on July 29th.

THE SWANSEA HOSPITAL.—The annual report of the Swansea Hospital, which has been recently issued, shows an adverse balance of £766, although the institution is most economically worked. The sum of £805 was received from extraordinary sources during the year, as compared with £1727 in the preceding year.

THE LANCET.

LONDON: SATURDAY, JULY 17, 1897.

THE holiday season is once more at hand, and once again we must repeat that the true holiday is that which occasions no strain and no anxiety. "Drive" is the curse of this century. We have lost the sense of repose. The capacity of passive contemplation has been preserved only by oriental peoples. We suffer from the exaggeration of the activity which has made our greatness as a nation. We are punished by the vice of our virtues. New diseases have arisen, or perhaps it would be more correct to say that diseases which were rare are now common, and these are almost all attributable to the extraordinary strain entailed by the modern exigencies of the struggle for existence. Great fortunes are amassed, terrible poverty follows in their trail, the "submerged tenth" appear as BANQUO'S ghost at the feast of the prosperous. Those who succeed have ever before them the alarming spectacle of innumerable failures, of unfathomable suffering. The poor suffer by reason of their poverty and the wealthy by reason of the dangers which menace their situation. Safe investments bring in hardly any interest, and where the interest is high the risk of loss is ever present. This it is which occasions the strain and causes what is colloquially called "driving." We now try to do in a few hours an amount of work which our forefathers leisurely accomplished in a much longer time. Mechanical contrivances, railways, the telegraph, the telephone, the bicycle, all conspire together to make us hurry in every detail of life, to leave us no time for reflection, to compel us to prompt decisions. Therefore, the strain of intense concentration is necessary so that we may be able to decide in a moment what in former times we might have contemplated at leisure and settled after calm deliberation. Among the working classes, though the hours of labour in the leading trades have been considerably reduced, it is found that the output on the whole has been greatly increased. This is not only due to improvements in machinery, but is also the result of the greater intensity of application. Machinery is very expensive and consumes much coal. The competition among the working men, as among the commercial classes, is most keen. To be secure in his employment—for there is the vast army of the unemployed outside ever ready to take his place—the workman must obtain from the machine he controls the maximum possible output in the minimum time. Hence the sense of "drive," which has enabled the chariot bearing British industry so often to win the race, though the victorious horses have so overstrained themselves as to sink prematurely to the grave.

While that class of disease due to bad sanitation is becoming more and more scarce in our midst, those diseases that result from nervous exhaustion are becoming more and more prevalent. What, then, under these circumstances, should be the object and purpose of a holiday? The answer is obvious—such rest as will recuperate the nervous system. Therefore, the first consideration is that the holiday shall be absolutely free from all anxiety, that there shall be no hurrying and no effort to do a great deal in a very little time, and that there shall be no competition, no rivalry, no attempt to excel or to outdo others. Unfortunately, the spirit of competition has spread even to our recreations. Medical evidence reaches us from all sides as to the injurious effects of injudicious and reckless bicycle riding. So in other out-door sports and athletic exercises recreation is converted into labour and pleasure into pain. Instead of playing to win health, how many play only for the satisfaction of beating a fellow player? Thus after over-straining themselves in work and business they overstrain themselves at play. Nor is this the only form of rivalry in recreation. The very mapping-out of a holiday excursion is often a deep-laid scheme to outshine a neighbour. During the whole winter the neighbour in question has described at various social gatherings the wonderful tour he and his family made last year in—let us say—Switzerland. His envious hearers have never been further afield than Margate or the Isle of Wight. They must now not only do as well, but even better. They will go further and see more. If the neighbour has contemplated the sunrise from the Rigi, they must at least look down the crater of Mount Vesuvius. Thus a lengthy journey is undertaken, involving expenses that are often beyond the financial means of the family, to see sights in which they take no real interest, but simply and solely because they want to do at least as well as, if possible better than, other acquaintances in their particular circle of friends. Such holiday tours entail a continuation of the strain and of the anxieties that are the inevitable concomitants of modern business. As the expenses must be limited, each town and each sight must be seen with undue haste and in a manner that causes unhealthy fatigue.

Of course, all action engenders reaction, and there are not a few families who seek to satisfy their self-esteem by proudly declaring that they will not allow themselves to be carried away by any such folly. They will not go to any fashionable place whatsoever. They will not brave the discomfort and fatigue of any continental tour. They will go to some utterly unknown country village, a long way from any railway line, where they will be topographically divorced from the life of great towns and from the noise and rush of both business men and holiday folk. This all sounds very wise, sedate, and reasonable. But we must not forget that habit is a second nature. For holiday-makers to be in a village where it is impossible to buy a newspaper; where postal communications are more difficult than if they were ever so far away on the continent; where there are no shops; where none of the comforts and luxuries to which they are accustomed can be purchased; where there is but one butcher, who only kills once a week, and where even the bare necessities of life are difficult to obtain, is a condition of existence which does not always engender that sense of contentment and perfect rest that characterises a healthy holiday. This, again, is not the ideal. All the habits of life are not to be thrown away by the mere hailing of a cab and the booking to the station nearest to some forlorn village. The chances are

Digitized by Google

that the holiday seeker will in a few days weary of his solitude. He will find his ordinary troubles replaced by the trouble to get something like the food to which he is accustomed and some sort of occupation that will satisfy his mind. The dweller in a great town does not realise how much he depends on the surrounding conveniences and civilisation. When he is suddenly cut off from all these the change is too great and sudden, and there is but little enjoyment in it.

What, then, is the ideal holiday? Fortunately, this cannot be stated in a sentence or even in a volume. If it were so easily described then everyone would want to do the same thing and go to the same place, and this would be a material impossibility. But what we have said can serve to indicate the principle that should govern the plan of the holiday. We suffer from excessive competition, from the "driving" which produces the nervous exhaustion that constitutes the most characteristic symptom of the nineteenth century. There must, therefore, be no competition, no feeling of rivalry with other holiday seekers, and no desire to boast on returning of the wonderful things achieved. If we play we must play for the sake of health and pleasure, but our pleasure must not be found in the pride of excelling someone else. If we walk, or cycle, or climb, or row, or run, we must do so because we feel inclined to take such exercise, because it agrees with us, and not because we want to go farther or quicker than someone else. There is, we repeat, too much competition in business; therefore there should be none in pleasure. Where fatigue commences pleasure is apt to pall and health to suffer. But while thus economising the physical forces of the body we must be equally careful with regard to those of the mind. To save the brain and the nervous system the holiday must be so managed as to involve no financial strain Its pleasures must not be darkened by the thought that too much money is being spent. We must not attempt more than we can easily afford, for the object of the holiday is rest, and there is no rest where money troubles threaten. Bearing these general principles in mind, it is for each individual to select that form of holiday which is most in keeping with his means, his tastes, and his proclivities.

No result of the late Jubilee celebrations is likely to be more lasting or more important than the feeling of friendship, mutual admiration, and mutual esteem which it has brought about between Great Britain and her colonies, among which a deservedly high place must at once be accorded in respect of patriotism, public spirit, and enlightenment to Australia. If Cape Colony has presented us with a battleship, it must not be forgotten that Australia, ten years ago, undertook to defray jointly with us the expenses of the Australian auxiliary squadron. To our colonies we send the most enterprising of our sons, and Australia in particular gives them a warm welcome; and from Australia, when they have won prosperity, they return to the old country with less readiness than from any other adopted home. There is something in the life, whether in town or the country, that fascinates them, and they remain. Australia, however, is a large continent, and if we cannot include every portion of it in our praise we do not condemn it as a whole on account of the delinquencies of what may not be one of its most important factors, for, as a matter of fact, just at the present moment Perth, the capital of Western Australia, is certainly not a conspicuous example either of patriotism, public spirit, or enlightenment in respect of matters of vital importance to the health and prosperity of its citizens and to the reputation of the colony.

It is true, we understand, that those who spend the public moneys entrusted to them by Perth citizens are endowing the township with public printing-works, with a mint of palatial design, and with an observatory, while a project for zoological gardens has been mooted; but although commending the desire to study other worlds implied by the observatory, we would suggest that Perth should observe its own condition and look elsewhere without requiring the aid of astronomical telescopes for the true paths to self-improvement. Perth at this moment is being seriously devastated by an epidemic of typhoid fever, and, setting aside private sources of information, if only a small fraction of what we learn from the local press is correct there seems no reason why Perth should not continue to be devastated for an indefinite period by typhoid fever or by any other epidemic that may once get a hold upon its people. Of the attack now raging suffice it to say that in one week there were fourteen deaths from this disease alone. The causes directly responsible for the condition of Perth are evident. The city has no efficient drainage system—no system at all, we believe, according to modern ideas; it has a water-supply not beyond suspicion at its point of origin, and liable to every kind of abominable defilement in and near the town; while its milk-supply is equally open to criticism. Concerning this last, the rigour of the supervision accorded to it, as well as its unusually intimate connexion with the water-supply, may be judged from cases detailed in the *Perth Morning Herald* of milk being sold containing 50 per cent. and more of added water, while the back yard of a deserted "dairy" was found to contain traces indeed of a cow, but stacks of empty condensed-milk tins! There is no record that the milk-dealers in these cases suffered any penalty or were even prosecuted for their share in the work of endangering human lives. With regard to drainage, the system which the city fathers of Perth appear to permit for the disposal of the natural refuse of a growing town is perhaps the system suggested by the naturally porous soil of the locality, but it is also primeval and primevally dirty. "Dry-wells" is the term applied to pits which are neither wells nor dry, but are simply holes in the sand into which every form of refuse, more or less liquid, is collected, until the solid or greasy constituents of the refuse, instead of running away, begin to coat the walls, which thus become impervious. Then the "dry-well" is boarded up and another is dug near by. More solid refuse, including fæcal matter, is carried to some distance from the city, and either buried at a small depth in the sand or treated in a place called euphemistically (or satirically) a "sanitary reserve," where some sort of burning is practised in the case of anything that will burn easily.

What will happen, we should like to know—and we advise the ratepayers of Perth to ask themselves—when the whole of the sandy area within reach has become so impregnated with filth that it will hold no more? Probably those in

Digitized by Google

authority are satisfied that "sufficient unto the day is the evil thereof." In this, in a sense, they are right, for the evil of Perth's insanitary condition would seem to have reached a point at which it will take many days to stay its course; but such an amiable policy of hope and trust must not be persevered in. The most elementary rules, not only of sanitation, but of decency, are being disregarded. Matters have reached a pitch at which the cleansing of back yards and the providing and emptying of privies are mere details. What is wanted is a complete and effective system of drainage, a code of sanitary laws, and a strong and independent body of men to enforce them. We do not insult the intelligence of Perth citizens by explaining that manure in a liquid form will percolate through sand and defile water springs, and that a heap of it lying exposed in a solid state will pollute the air. We do not suppose that they are blind to the fact that such things may cause and spread disease, and that in civilised towns, from motives of safety as well as for reasons of æstheticism, such methods of drainage are as obsolete as the indifference that permits them. But we do take it upon ourselves to advise Perth to get something done and done quickly. Perth has much in its favour in the way of situation, while it is a city of modern origin, and belonging, as it does, to a go-ahead colony, should be ready to employ all the necessary appliances now at the command of the modern sanitarian. Perth has, moreover, a brilliant example comparatively near to it if what we hear of Coolgardie, that most recent of mining centres, is true. At Coolgardie every effort seems to be made to overcome the natural difficulties that beset sanitation and local government in a new and necessarily rough-and-ready community. What Coolgardie can do surely Perth can do, and we look to public-spirited citizens to ensure that an early start is made. True public spirit will postpone the erection of observatories, mints, and even printing-houses, and will taboo the establishment of zoological gardens until the life and health of the city has been safeguarded. True public spirit is just before it is generous. It will disregard the fact that sewers are costly without being showy on the surface. It will support its sanitary officers through thick and thin, without studying the favour or disfavour of the dirty and ignorant, and it will so build up in the city, in the inhabitants of which it is found, memorials of nineteenth century progress worthy to rank with any of the more visible monuments of Jubilee loyalty and enthusiasm.

THERE is no one who will not have read with the greatest satisfaction the righteous sentences pronounced last week by Mr. Justice HAWKINS upon five scoundrels convicted of blackmailing. Three of them, GRANT, COULTON, and THORPE, had terrorised and unhinged the mind of their miserable victim to such an extent that they not only got large sums of money from him, but rendered his life so wretched that his health is probably permanently undermined. Justice, however, though it would seem *pede claudo*, has overtaken them; two have received sentences of penal servitude for life and the third for fifteen years. The other two, who had acted a shade less villainously towards another victim, were punished with ten and eight years penal servitude respectively. These are heavy sentences, yet not one whit too severe, and not so many years ago the legal punishment for this class of offence was death.

Blackmailing is, we regret to say, a crime essentially human, and, more than that, one belonging to the higher civilisation. The primitive man if he wanted his neighbour's goods or his wife simply took them; if his neighbour resisted he hit him on the head or was himself killed. It was the recognised method of procedure—one that everyone was liable to and one that men shared with animals; but with advancing refinement the bestial element was eliminated, and that side of human nature which theologians say is derived from the great Accuser came to the fore, and instead of entering into a brutal fight, where very possibly he might come off second best, the refined blackguard said to his victim, "Unless you will give me so much I will render your life utterly wretched; I will accuse you of nameless crimes; friends, position, honour will all slip away, and you will pray for death as a release." The criminal of this class is a keen judge of human character, and selects his victims with great care, so that he has two advantages on his side. First, the fact that there are a certain number of persons who are so dumbfounded by an accusation of this sort that though they may know it to be utterly false, yet they have not the courage to fight against it; secondly, the fact that there are perhaps few persons in the world who have not got a skeleton of some sort in the cupboard which they would rather not have exposed to the eyes of others. And so the weak-minded man is led to give way in the first flush of terror and disgust, thinking to stave off some disgrace—he knows not what—until the penalty for silence gets heavier and heavier and his life more and more miserable, when he at last does what he should have done at once, seeks the aid of the law and, as in the two cases upon which we comment, stands up in court before the eyes of his fellows a man of unblemished character.

We are led to dwell upon these particularly odious crimes because they have a special interest for us as members of the medical profession. Of all professions ours is the one most open to attacks of this kind; charges are constantly made against medical men which are most easy to bring and equally hard to refute, although we are glad to say that those against whom they are brought almost invariably act so that the matter is fought out in court. At first sight it might often seem worth while for a medical man to submit to blackmail; legal proceedings are very long, always expensive, and in cases of this sort not particularly pleasant for the defending side. Small wonder, then, if the busy practitioner is sometimes tempted to buy silence at the price demanded. It is a temptation, however, to which he rarely yields, for he knows very well that the blackmailer is a very vampire who returns time after time until he has drained his victim dry so that unless he is met and fought at the outset he becomes more and more difficult to shake off. Everyone should remember this point and medical men of all others, for their honour is their very existence; and if they have not time, or think that they have not, or are too poor to battle single-handed, there is an easy way out of that difficulty—namely, by joining one of the societies organised for medical defence. Let anyone read the reports of these societies and he will see that in nine cases out of ten the blackmailer when confronted with the society retires

Digitized by Google

precipitately from the case. Let no one think either that on account of position, or age, or experience, or the nature of his practice he is exempt from the danger of attack. "*Hodie tibi, cras mihi*," is the motto for every one of us, and no one knows whence the bolt may fall. The medical defence societies are doing good work even with the small amount of power they possess, but we must wait and strive until our own profession is as united and as well organised as that of the law. The blackmailing of a lawyer is an unheard-of occurrence; firstly, he is far too alive to his own interests to make such a thing possible; and, secondly, he belongs to a profession the very name of which is objectionable to criminals. Let us, then, as medical men lay down our petty differences, and in so doing preserve for ourselves, not only a living wage, but our honour and reputation. The stronger we are the more wisely and the better we shall be able to use our strength, not only for our own profit and renown, but also for the benefit of the community which we serve.

AN interesting Blue-book has recently been issued by the India Office entitled "Further Papers relating to the Outbreak of Plague in India." Amongst other matters which it contains there are details of a number of experiments as to the results of the inoculation of preparations of different grains, &c., such as wheat, flour, rape-seed, &c., with cultivations of the plague bacillus; and the Governor-General of India in one communication states that during the sittings of the Venice Conference in March last the Government of Bombay telegraphed to the British delegation to the effect that grain purposely infected did "not permit of the existence of the microbes for more than four to six days." He now adds that the Government of India are advised that the experiments as to this are not conclusive, "since the loss of pathogenic property may be demonstrated without the loss of vitality, so that the bacilli may under favourable local conditions, re-acquire toxic properties." Points such as these have high scientific interest; but we cannot help thinking that when the question arises of announcing such possibilities in connexion with matters of trade and commerce, which are of vital importance to India and even to our own country, it would be better to wait until some measure of certainty had been attained. Nearly all measures of restriction which have turned out to be useless in practice have been based on theories involving possibilities as distinguished from certainties. It is, indeed, extremely doubtful whether a carefully designed laboratory experiment in which a given microbe is purposely inoculated into specially contrived preparations of a certain article finds any real counterpart in ordinary trade transactions carried on by persons who are presumably in health; and the fact remains that notwithstanding these experiments no case or cases have been known in which the abundant exports of grain from Indian or other plague-infected ports have been identified with, or even reasonably suspected of having been followed by, the production of plague.

Another similar matter was, according to the Blue-book, brought under the notice of the Local Government Board by the India Office. The latter department, whilst awaiting the results of experiments in India as to "the behaviour of the plague microbe in wool," desired to know, in the interests of certain British manufacturers, if the scientific advisers of the Local Government Board could express an opinion whether bales of wool from Bombay or Karachi would carry risk of plague to people who might handle the wool in England. Here again the question arises as to whether laboratory experiments and intentional inoculations can be interpreted in such a way as to apply to trade processes carried on under ordinary circumstances and with presumably healthy people. The whole histor of plague in Alexandria and elsewhere is entirely opposed to the theory of the disease being conveyed by goods which are dealt with as articles of commerce; and thousands of bales of cotton, for example, have been regularly delivered in European ports from plague-infected ports, and even by means of plague-infected ships, without the occurrence of plague in the ports of arrival or amongst those dealing with the cotton. And we cannot but feel that evidence of this sort should altogether outweigh the discovery, after a certain number of days, of the plague bacillus in a given sample of cotton which had been purposely inoculated with it under laboratory precautions by an expert bacteriologist.

We are, therefore, in no way surprised to find that the India Office were informed that the medical officer of the Local Government Board was not aware of any evidence to show that there was danger to the United Kingdom merely because of the arrival of bales of wool from ports where plague was prevalent, and that, in his judgment, the discovery of the plague bacillus after a certain number of days in an article that had been purposely inoculated with that bacillus ought not to be regarded as affording proof that the article in question, whether it be wool or any other substance, was likely in the ordinary trade processes to convey that infection. This was the attitude which was adopted by the British delegates at the Venice Conference, and it very largely aided them in carrying their point even in the face of suggestions of possibilities based on laboratory work and intentional inoculations. As a result trade and commerce will be but little hampered by the conclusions embodied in the Venice convention; and hence we should be sorry to see suggestions bearing in an opposite direction emanating from one of our own dependencies. When we have proof that trade processes involve danger, then will be the time to restrict those processes, and, in the meantime, we should prefer to see the results of bacteriological work in laboratories discussed apart from the question of such trade operations as are concerned with imports and exports.

Annotations.

"Ne quid nimis."

THE PLAGUE IN POONA AND THE LATE OUTRAGES.

THE more we learn of the facts connected with the late tragedies at Poona the more strengthened we feel as to the substantial correctness of the position we took up last week in regard to the recent events in India. There is, and there can be, no desire on the part of either the authorities in India or of this country to stifle any fair criticism or apply "the closure" to any reasonable, if mistaken, expressions of disapproval in regard to themselves or

Digitized by Google

their acts. The natives of India generally are a docile and law-abiding, but an ignorant, excitable and highly credulous people, among whom public opinion, as we understand the term, has no existence, and the masses are consequently very much at the mercy of a disaffected minority, who utterly disregard the truth or accuracy of any statements they may make. It would be absurd and unjust to say that there are not numbers of intelligent, educated, and philanthropic Hindoos and Mahommedans in the country, for, as everybody knows, there are. We are not speaking of such as these, but of the masses of poor natives who are ignorant, superstitious and credulous, and conservative to a degree, and they make up a highly inflammable material if only the right kind of match be applied. Poona, the capital of the Deccan, is a well-known hotbed of disaffection, and the application of the necessary hygienic measures for dealing with the plague afforded an opportunity to the disaffected classes to indulge in all kinds of misrepresentation for the purpose of prejudicing the Government authorities and inflaming the fears and passions of the native races against them. The search parties consisted of native as well as European troops, and natives were invited to take part in all that was done—officers, medical and military, female medical practitioners, and nurses lent their aid; and it is inconceivable that under such circumstances any of the alleged outrages on the part of soldiers could have taken place; nor did any revengeful acts on the part of the native population occur at the time or immediately afterwards. It was not until time had been afforded for the fabrication of maliciously false reports that any vindictive spirit was exhibited, and that is always the danger in India. But there is no reason for people in this country "to lose their heads" on the subject. It is not the beginning of a fresh mutiny—indeed, there is not the necessary native organisation for creating one on any large scale, although manifestations of ill-feeling against our government must always be regarded with thoughtful suspicion and some possible anxiety. If we really believed that the natives of Poona had any just cause of complaint they would have our sympathy and support, but all the independent reliable evidence is to the contrary effect. The professors attached to Indian colleges who are now in this country should be prepared to substantiate their charges or take the consequences; at least, so it seems to us. The measures adopted for the suppression of the plague in Poona appear to have been eminently successful; but, notwithstanding all the care and consideration that may be bestowed, their application must, we fear, be always unpopular and distasteful. Still, we should spare no effort to do all we can to avoid wounding the religious susceptibilities and caste prejudices of the native population. India has been sorely tried of late by plague, pestilence, and famine, followed by earthquake; and it is quite possible that an ignorant and superstitious people may regard these as so many signs adverse to our rule.

KISSING THE BOOK.

ON July 5th Sir Walter Foster repeated his question in the House of Commons as to the English form of oath, and asked the Attorney-General whether it was his intention to make any proposals for amending the law so as to abolish the objectionable practice known as "kissing the Book." Sir Richard Webster repeated his reply that the sanitary objections to the present method of administering the oath had in his opinion been somewhat exaggerated. He also expressed his personal belief that the option of swearing in the Scotch form, which is becoming every day more generally known, was sufficient. He added in conclusion that it was not the intention of the Government to amend the law, at any rate during the present session. On the first and second points we must observe that the danger of infection is a matter not of opinion but of fact, whether we regard the risk as conveyed by the Book from mouth to mouth or as a mediate form of contagion in cases of epidemics. In the epidemic of small-pox in Warrington some years ago a solicitor, fearing that he might be infected by a previous witness from an infected house, claimed to be sworn with uplifted hand, but was refused permission by the county court judge, who was ignorant that in doing so he was violating the law and depriving the witness of his just rights. More recently in the epidemic of small-pox at Gloucester some jurors objected to kiss the book on similar grounds, and were permitted to swear with uplifted hand. Notwithstanding these exceptions, and the fact mentioned by Sir Sherston Baker, Recorder of Barnstaple, that there is no legal authority extant for kissing the book, it is still, we assert, practically compulsory on the large majority of witnesses, most of whom are wholly ignorant of the Act of 1888 and its fifth section; while of the few who know it only a very few claim the privilege, owing to an intuitive dislike to be singular and to give trouble. Sir Richard Webster is also reported to have stated that notices had been placed in all courts showing witnesses the provisions of the Oaths Act, 1888, which permits them to take the Scotch Oath. This is a fact of which we were wholly unaware. As the assizes are now being held throughout the counties of England and Wales it will be interesting to ascertain the result of this publicity. Apart from the question of infection the English form of oath stands condemned as an uncleanly mode of adjuration; it has also been condemned by an eminent English judge as being wholly unintelligible to children, and, he might have added, to many adults. Those who respect the religious sanctity of an oath have condemned it as wanting in solemnity. During a period of twelve years we have repeatedly urged its abolition and the substitution of the Scotch form as the uniform mode of adjuration. It remains now to be seen whether the public, guided by the press, will recognise the desirability of this reform.

FRACTURE OF A VERTEBRAL ARTICULAR PROCESS.

IN the June number of the *University Medical Magazine* of Philadelphia Dr. John K. Mitchell publishes a case of this very unusual injury. A woman, aged thirty-two years, in moving backwards stepped with her left foot into a hole and wrenched her spine in the effort to recover her balance. The spine, especially in the lumbar region, became very tender, and she suffered from sciatica in both legs so severely that the operation of stretching the nerve on the most painful side—the right—was performed, but without relief. Five years after the injury she was still suffering from paroxysms of pain accompanied by twitchings and involuntary movements of the legs, especially if she lay on her back. For months she had to sleep propped up, in order to prevent them. Movements, such as rising, bending, especially to the right, standing on the right foot, or walking on an uneven surface, caused distress in the cervical and lumbar regions and in both sciatic nerves, especially the right. The knee-jerks were diminished, especially the right. From the waist down the whole spinal region was very sensitive, and on the right side, at the level of the third and fourth lumbar vertebræ, was a spot so exquisitely tender that it could not be touched without the patient crying out. An exploratory operation was performed by Dr. J. William White. The patient was placed in the prone position and an incision made over the spinous processes of the third, fourth, and

Digitized by Google

fifth lumbar vertebræ. The muscles were dissected first from the right and then from the left side of the spinous processes. Nothing abnormal was found. On inserting the finger, however, along the lateral aspect of the superior articular process of the fourth lumbar vertebra in order to reach the intervertebral foramen, a piece of rough bone, a portion of the process, broken off and displaced forwards, was felt. Enough periosteal attachment remained to prevent necrosis. The fragment was removed partly with the gouge and partly with the curette, care being taken not to injure the nerve. The patient was relieved at once by the operation. Next day her bed could be shaken vigorously, although she had formerly experienced agonising pain on the slightest movement. Complete recovery followed.

AN ANCIENT GREEK HEALTH RESORT.

THE ancient Greeks, at all events after heroic times, were not always in the aggravatingly robust state of health that is the popular idea of their condition. Human nature is very much the same all the world over and at all times. There were many health resorts where sufferers were treated by Asklepios himself or more frequently by his qualified assistants—i.e., the priests, and the *modus operandi* at these institutions formed the subject of a very interesting lecture by Miss J. E. Harrison, recently delivered before the University Extension Society. The lecturer gave an account of what was perhaps the earliest known medical school—namely, that of the centaur Chiron. Here the children of the heroes were taught simple surgery, riding, gymnastics, the rudiments of music, and, in common with the ancient Persians, to speak the truth, the last being a branch of education which has fallen into disuse among both nations. The chief subject of the lecture was, however, the shrine at Epidauros which has recently been excavated and is in fairly perfect condition. The temple and the long corridors where the patients slept are all there, but the holy well alluded to in many inscriptions has not been found. Besides these the patients have left memorials of their cures carved upon stones, a very full one being that of a Roman gentleman, and we are able, through the courtesy of Miss Harrison in supplying us with the original Greek, to append a translation. "I, Marcus Julius Apellas, of Idrias and Mylasa, was summoned by the god, as I suffered from a variety of complaints, and especially dyspepsia; and as I was on my way through Aegina he ordered me not to worry so much about myself (μὴ πολλὰ ὀργίζεσθαι). When I arrived at the shrine he told me to go about for two days with my head covered up, and these two days it rained. He also prescribed for me cheese and bread with celery and lettuce, to wash myself by myself—i.e., without the help of the shampooer—to drink lemonade made from citrons, to go to the fountains in the baths and rub myself against the wall, to run and do gymnastics, to walk in the portico, and to exercise on the trapeze, to rub myself in the sand and go barefoot. Also before I went into the bath I was to pour some wine into the warm water; I was to shampoo myself, but all the same I had to give an *attic* to the bath man. I was to sacrifice to Asklepios, Epione, and the Eleusinian goddesses, and to drink milk mixed with honey. And one day when I was drinking milk alone he said, 'Put honey in your milk and you will get the bowels open.' And when I implored the god to make me well quickly so that I could get home I had a vision in which he ordered me to rub my body all over with mustard and salt, and I seemed to go down to the springs by the shrine, and a boy went before me with a smoking censer, and the priest said to me, 'Now you are well and you must pay your fees.' So I did as the vision directed, and when I rubbed in the mustard and salt it hurt, but when I washed it off it did not hurt any more, and this happened on the ninth day after I came, and he touched me on the right hand and on the breast. And the day after, as I was sacrificing the flame leaped up and burnt my hand so that a blister came up, but my hand soon got well. And as I stayed on there he told me that anise and oil were good for a headache. I had no headache then, but some time afterwards when I had been studying I had a headache, and I used the anise and oil and the headache disappeared. He also told me to gargle my uvula with cold water (for I had consulted him on this point too), and the same treatment for the tonsils. And he told me to write all these matters down, and so, grateful and restored to health, I went away." The naïveté of this narrative is delightful, but the treatment is eminently practical. Apellas is very like the ordinary patient—the sort, we mean, who, having paid his fee, says, "Oh, by the bye, there's one thing more I want to ask you. I often have," &c.

MEMBRANOUS CONJUNCTIVITIS IN A CASE OF MEASLES.

IN a case recently published by Dr. H. A. Brennecke, this unusual complication, which clinically resembled true diphtheria of the conjunctiva, was observed.[1] The patient was a boy, aged three years, one of a number of patients attacked by measles. He exhibited the usual symptoms of the disease. On the fifth day the urine contained albumin, and hyaline and epithelial casts. The right conjunctiva was markedly injected. Next day this was more intense, and the lower lid was much swollen and showed a heavy white exudation. On the eighth day the upper lid was affected, and there was an abundant milky discharge. On the tenth day the patient was restless and refused nourishment; the back and shoulders as well as other parts exhibited diffuse, irregular, red patches, which did not disappear entirely on pressure. The right cornea was hazy. There were numerous subcrepitant râles in the lungs, and signs of consolidation in the right lower lobe. Death took place on the twelfth day. Repeated examinations of the membrane covering the conjunctiva failed to show the diphtheria bacillus, but a microbe having the characters of the streptococcus pyogenes was cultivated. It was also found after death in the blood and viscera. Dr. Brennecke concludes that the streptococcus was the cause of the membranous inflammation of the conjunctiva. He cannot decide whether the microbe primarily infected the conjuctiva or reached it through the blood from some other source, such as the throat.

METALLIC CHEESE.

IT has been a common theme of congratulation by not a few writers and philanthropists that the days are over when people were poisoned by the indiscriminate practices of the adulterator, and that now they are only cheated. What will be said then of the announcement that both the salts of zinc and lead are used in the preparation of cheese? "Cheese spice" is the delectable name of crystallised sulphate of zinc, which, according to Mr. Allen, the public analyst of Sheffield, is used to prevent the heaving and cracking of cheese. Worse still, Mr. Stoddart, another public analyst, has described a sample of Canadian cheese in which he found metallic lead, and it is probable that the highly poisonous acetate of lead was employed for the same purpose as sulphate of zinc. This is, indeed, a revelation, and vestries and other authorities would do well if they instructed their inspectors to secure samples of cheese with the view of setting this very disturbing question at rest. In old times, when substitutes were not, most excellent cheeses

[1] Medicine, Detroit, June, 1897.

Digitized by Google

were made which required the addition of no other antiseptic than homely salt, and there is no reason why cheese should require any further treatment now. We trust that the facts brought to light by the two analysts just mentioned will lead to the permanent suppression of such an abominable practice.

STENOGRAPHY FOR THE MEDICAL MAN.

THE *Phonetic Journal*, in congratulating Sir W. R Gowers upon the honour Her Majesty has conferred upon him, naturally refers to his work in connexion with shorthand as well as to its influence upon his medical work. The characteristic of the work of Sir William Gowers is, our contemporary avers, accuracy. "This quality has been fostered by the habit of careful and correct observation. That habit in turn has been helped by the persistent practice of instantaneously recording the observed fact. The acquisition of stenography in his student days, the rapid recognition of its power to help him in his professional studies and in his professional work, the determined mastery of it and the continuous use of it have multiplied his naturally enormous capacity for work, and strengthened and intensified his habits of careful and correct observation." It is a noteworthy fact that another recipient of knighthood on the occasion of the Diamond Jubilee, Sir William Thomson, President of the Royal College of Surgeons in Ireland, is a writer of shorthand and as staunch an advocate of its use in medical work as is Sir William Gowers.

A NEW FEVER HOSPITAL FOR LONDON.

THE ceremony of the opening of the Park Hospital, Hither-green, Lewisham, on Monday last, by the Prince and Princess of Wales, successfully inaugurated the most recent and extensive of the large group of fever hospitals which have arisen under the ægis of the Metropolitan Asylums Board. Of the ceremony itself there is no need here to speak in detail. Suffice it to say that it once more afforded opportunity for testifying to the keen interest and sympathy which their Royal Highnesses evince in all matters that concern the public weal. The speech made by the Prince of Wales struck the right note and showed how fully he recognises the importance to the community of the work carried on by the Board as well as the manner in which the Board is fulfilling its trust. After the ceremony the large gathering of visitors were enabled to inspect the vast range of buildings, which may be taken as representing the most complete and best approved style of construction of an infectious diseases hospital. The site upon which the hospital is built is an elevated one, and is close to the Hither Green Station of the South-Eastern Railway. It consists of twenty acres of ground, and the hospital is intended to accommodate 548 patients, distributed as follows: 48 wards for 368 scarlet fever cases, 24 wards for 120 diphtheria and enteric fever cases, and 36 isolation wards to accommodate 60 patients. The staff will consist of 316 persons, including the medical superintendent, 5 assistant medical officers, matron, housekeeper, 2 superintendent nurses, and 191 other nurses. The ward pavilions are disposed on either side of the central administrative block, each pavilion consisting of two floors containing three wards, access to the upper floor being by an external staircase opening from the covered ways which connect all parts of the building. The architect, Mr. Edwin T. Hall, is to be congratulated upon the admirable manner in which every detail has been planned. The arrangements for heating and ventilation of the wards are in some respects novel and promise to be highly efficient. The water-supply will be furnished by wells sunk in the chalk, the water being pumped into a softening apparatus and thence to the water-tower, which forms a conspicuous feature in the centre of the blocks of buildings. The laundry and kitchens are well arranged, whilst the nurses' home, placed on the northernmost part of the site, consists of three houses connected by glass and iron corridors on every floor. In the important matter of drainage, in the construction of water-closets, lavatories, &c., no detail has been omitted to render the institution free from sanitary defects. The provision of this additional isolation for fever in the metropolis reflects much credit on the Metropolitan Asylums Board, whilst the care and pains taken in the construction and arrangements make this hospital worthy of London and a boon to its inhabitants. In the nine hospitals at present in operation there is provision for 4254 patients. To this will now be added the 548 beds at the Park Hospital, and 520 in the Grove Hospital now in course of construction at Tooting. A convalescent hospital is also to be erected at Carshalton for 700 patients. There will then be accommodation for 6022 fever and diphtheria patients, whilst the hospital ships, Gore Farm Hospital, and a proposed new hospital at Joyce-green, near Dartford, will bring the provision for small-pox up to 1892 beds.

THE INTER-MARRIAGE OF DEAF-MUTES.

A LETTER in another column reminds us that the question of how far acquired deafness is hereditary is a very interesting one to the community and therefore to their medical men. It is an unfortunate fact that deaf-mutes tend, perhaps by a common sympathy or from association during early years, to inter-marry. We say unfortunate, for marriages between congenital deaf-mutes or others with congenital nerve defect tend to produce a family with some members mentally afflicted. It is, however, otherwise among persons of sound brain power, who early acquire deafness as a result of scarlet fever or other accidental disease of the organ of hearing and consequent mutism—the ear, not the brain, being primarily affected. Those who tend to transmit deaf-mutism to their offspring are congenital deaf-mutes, not those acquiring deafness as a result of disease or accident; a man with disease of the middle ear is probably no more likely to have deaf children than a man blind from accident or disease to have children with defective sight. The census record shows that among deaf-mutes the male ratio is much higher than the female rate at each and all ages; and if it is true, as is commonly accepted, that congenital defects are more commonly transmitted to a son through the father, a man whose father was deaf from acquired ear disease in childhood, even if his mother were congenitally mute, is not likely to transmit such tendency to his children. The moral of these remarks is that it is unadvisable to train deaf boys and girls in mixed classes after the age of twelve or thirteen years.

THE HEALTH OF THE ARMY IN INDIA.

A BILL has been introduced into the Viceregal Legislative Council repealing the Cantonment Acts of 1895 and untying the hands of the Indian Government by giving it the same powers in respect of venereal disease that it has in the case of other infectious and contagious disorders. We notice, by the way, that the Ladies' National Association held a meeting at St. Martin's Town Hall on the 9th instant and took up their parable in an opposite sense. As at present, the Government of India is legally empowered to take energetic steps for preventing or limiting the spread of small-pox, cholera, and typhoid fever, but has no power to deal with the more common as well as gravest of all the contagious diseases that can afflict humanity—namely, syphilis. We need not repeat what we have already said on this subject, nor is there any

Digitized by Google

special reason for further considering it until we are more fully acquainted with the exact nature of the proposals of the Indian Government. The Bill is, no doubt, framed in accordance with the instructions embodied in the dispatch forwarded by Lord George Hamilton to that country, and the Secretary of State's proposals were so studiously moderate in their nature that many people regard them as likely to fall short of what is required for dealing effectively with the evil. Be this as it may, it is unwise to legislate in advance or excess of what is likely to be supported by public opinion. Legislation on such a subject is attended with great difficulties and has many pitfalls for the footsteps of unwary legislators. We can only rejoice meanwhile that something in the shape of an earnest attempt to deal with a terrible evil has been made, and that a very decided and wholesome change has taken place in the state of public feeling in regard to it. That it is absolutely necessary for something to be done to limit the spread of this scourge is generally admitted. The Commander-in-Chief, Major-General Sir Edwin Collen, and the Viceroy of India spoke strongly in favour of the Bill. The Viceroy expressly said that he took his full share of responsibility for the measures which the Government of India proposed to adopt and of which the Bill was a part; and he added that whatever might be thought of the conduct of incontinent persons, no one with a scrap of humanity would hesitate to take any measures in his power to control and check the progress of a disease so insidious and terrible as regards them, and so far-reaching as regards many innocent and helpless human beings. On the score of morality Lord Elgin also considered his position equally clear.

THE ROYAL COMMISSION ON TUBERCULOSIS.

FURTHER sittings of this Commission were held at No. 7, Whitehall-place on July 8th, 9th, and 12th, Sir Herbert Maxwell being in the chair. The following witnesses were examined: Mr. Morgan Hopkin, of Swansea; Mr. Pearson and Mr. Hides, of Sheffield; Mr. Ward, of Middleton, near Manchester; and Mr. Berwick, of Bradford, all of whom represented various butchers' associations, and gave evidence as to direct personal loss from the condemnation for tuberculosis of the carcasses of animals which had been bought as apparently quite healthy. Other witnesses called were Mr. Davies, medical officer of health of Swansea; Dr. Harvey Littlejohn, medical officer of health of Sheffield; Mr. Hedley, chief inspector of the Irish Privy Council, veterinary department; and Mr. Sinclair, superintendent of exports for the Victorian Government. This, we understand, concludes the evidence which the chairman proposes to call; but before considering the report he intends, with other members of the Commission, to visit a few towns in the United Kingdom to see the method of meat inspection adopted in them.

POISONOUS "HOKEY POKEY."

As with ice-cream, it is not surprising that there should be considerable obscurity surrounding the composition of that largely-consumed sweetmeat which is euphemistically known as "hokey pokey." Last Tuesday an inquest was held in the Islington Coroner's Court on the body of a child aged eight years. She had purchased some "hokey pokey" in the street. Two days later she died, after suffering from acute digestive disorder and presenting the usual symptoms of irritant poisoning. How long are poisons to be disseminated in the street in this most reckless way? Nearly twenty years ago THE LANCET Commission on the Sanitary Condition of the Italian Quarter,[1] reported how filthy was the environment under which ices were frequently compounded, and if the authorities cannot trace the ingredients to their source, surely they can at least see that the preparation of these edibles (*sic*) are carried out with the strictest attention to sanitary requirements. Every barrow-vendor of ices or, indeed, of any other article of consumption should be registered and compelled to carry his registered number on a metal label like the cabmen and omnibus drivers and conductors. In this way the men dealing out poisonous stuff in the street could be traced, and thus some amount of control over these "itinerants" would be exercised. Some step in this direction is, at any rate, very much needed, especially when the increasing number of deaths from this cause is considered.

[1] THE LANCET, Oct. 18th, 1879.

COFFEE-PALACES AND COFFEE.

MOST connoisseurs have despaired of ever obtaining coffee infusion in England of the fine character and aroma of that prepared on the continent, and especially up country in Norway, but we may at least demand that a beverage that is called coffee should contain a certain proportion of the article the name of which it bears. Otherwise coffee may as well be given up for ever. Yet coffee properly made fills an important place in the dietetic category. It is refreshing and stimulating, with a distinct tendency to arouse from a state of stupor and lethargy. It is, in fact, in this connexion that it is sought, though it may be unconsciously. It is, in short, anti-narcotic. According to recent analyses published in the Proceedings of the Society of Public Analysts, some coffee-palace coffee infusions must be practically destitute of those properties which mark coffee as an agreeably refreshing and stimulating beverage. The average amount of caffeine—the crystalline stimulating principle of coffee—in infusions obtained at several establishments in London showed that instead of containing 10 per cent. of coffee they contained very little more than 2 parts per 100. The result of this shocking attenuation means that the infusion contained only a fourth part (0·026 per cent.) at the most of the proper amount of the valuable and active constituent of coffee which gives the beverage its restorative character. In an investigation made by ourselves[1] we found that an infusion made by adding two ounces of coffee to a pint of boiling water (equal to a 10 per cent. infusion) contained 0·11 per cent. caffeine. Doubtless in certain cases coffee-palace coffee, though attenuated from this point of view, possesses plenty of "body" owing to the balance being made up of chicory, milk, and sugar. But these things are not coffee or in any sense to be considered as compensating substitutes. The customer supplied with such stuff is, in our opinion, distinctly defrauded, and it is time that the Food and Drugs Act was brought to bear upon this system of cheating. A systematic raid on the part of the officials entrusted with the carrying out of the Acts would soon put an end to this fraudulent practice, and the sooner such a measure is taken the better.

[1] Vide THE LANCET, July 4th, 1894.

FOUR GOOD WOMEN.

ON June 9th last Her Majesty the Queen personally bestowed the decoration of the Royal Red Cross upon Sister Mary Helen Ellis, Sister Mary Stanislaus Jones, Sister Mary Anastasia Kelly, and Sister Mary de Chantal Huddon, "in recognition of their services in tending the sick and wounded." This little ceremony at Windsor recalls an early incident in the history of the development of military nursing, a history which practically belongs altogether to the present reign. The four ladies above mentioned are the survivors of a band of eight Sisters of Mercy who served as nurses during the Crimean War. In October, 1854, five sisters, responding to an appeal of the Right Rev. Dr. Grant,

Digitized by Google

then Roman Catholic Bishop of Southwark, set out from the Convent of Mercy at Bermondsey, and, joining Miss Florence Nightingale in Paris, accompanied that lady to Scutari. A year later another party of three Sisters from the same institution arrived at the big hospital at Scutari. These eight ladies, of whom four now survive, worked under the direction of Miss Florence Nightingale at Scutari and at Balaclava until July, 1856, when they returned to London. They were not, however, destined to return permanently to scholastic work at Bermondsey, for in the same year they were asked to assist in the establishment of a small hospital of fifty beds which was at that time opened in Great Ormond-street for the relief of women and children belonging to that large class of sufferers who, by reason of the hopelessly fatal character of their disease, or on account of the prolonged nature of the treatment which they require, are no longer admissible to the large general hospitals. Under the title of the Hospital of St. John and St. Elizabeth the useful work of this charity, started with the help of the Sisters of Mercy who had been trained as nurses at the seat of war, has been carried on by nurses of the same Order until this day, and three out of the four sisters who have just been decorated by the Queen are still engaged in the administration of the hospital.

THE JUBILEE OF "LE SCALPEL."

THE well-known Belgian medical journal, *Le Scalpel*, published at Liége, has just completed the first fifty years of its existence, during which it has striven, by no means unsuccessfully, to maintain the honour, to cultivate the science, and to advance the interests of the profession in Belgium. Its founder, the late Dr. Festraerts, was a man of great capacity for originating and successfully carrying through struggles on behalf of those whose cause he had made his own, and, like other similar reformers, had often plenty of bitter enemies both in the profession and outside it. The forces that were several decades ago ranged against the *Scalpel* presented many features in common with those which were employed against THE LANCET and its Founder in the twenties and thirties. We congratulate Dr. Dejace, the present editor, on the position his journal occupies and on the energy with which he exposes abuses and seeks to remedy them in the interests of his brother practitioners.

A SAD STORY OF THE SEA.

THE daily press recently contained a report of a shipwreck under circumstances which reveal an amount of inhumanity displayed not only by laymen, but by a medical man, which we are glad to say is exceedingly rare. An English ship laden with sugar was going from Java to Delaware Breakwater, and very soon after leaving Java fever broke out, which eventually attacked every person on board. Eleven deaths occurred, leaving only ten people to work the ship, the second mate being in charge, and he decided to make for Mauritius, but was only able to get as far as Rodrigues Island, where he dropped anchor and, as it is inhabited by civilised beings, naturally thought he would be able to obtain medical advice and other assistance. The island is inhabited by French Creoles, but the governor and the surgeon are said to be Europeans and to be able to speak English. The pilot put off in his boat, and returning spread the report that yellow fever was on board. As no assistance came, the officer in charge, Mr. Rich, determined to land his passengers and crew, fearing that the ship would go to pieces, but on trying to land they were met by the governor and other inhabitants who threatened to fire on them if they persisted in landing. The only thing to do then was to row back to the ship, which they accomplished with great difficulty, and that night the ship was driven on to the rocks and began to break up. The Rodriguans at this juncture were apparently ashamed of their inhumanity and sent a boat manned by the pilot and some blacks which took off the survivors, landing them on a small sandy island separate from the main island and quite uninhabited. Here they were kept for twenty-two days with no shelter but a hut made of leaves, provisions being conveyed by a small boat and landed on the island. They had no medical assistance, but the surgeon put off in a boat after about a fortnight, stopped some distance from the shore, and examined them through opera glasses. After three weeks the monsoon set in and the Rodriguans, fearing that the islet would be covered by the sea, removed the shipwrecked people—now reduced to eight, including a woman and a baby—to the main island, where they were kindly treated for two months. After this they went to Mauritius, where they met with every possible attention. If this story is true we cannot pretend to explain such abominable behaviour. That laymen might be frightened by the occurrence of a possibly contagious fever is perhaps natural, but that any medical man should be so grossly neglectful of his duty is incredible. We are not told to what nationality he belonged, but whatever it is, if the account given be correct, his country has no reason to be proud of him.

COLOUR PHOTOGRAPHY.

IN THE LANCET of Feb. 6th we announced that a photographic process had been discovered by which a picture was produced chemically, with the natural colours to some extent faithfully portrayed. The nature of the process still remains a mystery to the general public, but in an interesting letter published in *Nature* of July 8th Sir Henry Trueman Wood, to whom the inventor has confided the details of his process, gives some assuring particulars as to the genuineness of the method. The selective action claimed by the inventor does, he says, exist, and the colouring matters applied to the photographic print have a certain tendency to attach themselves to those portions of the print which would be of a similar colour had the image been reproduced in natural colours. Further, the colouring matters, when applied in succession, do so combine or react on each other as to reproduce approximately the tones or tints of the original. A special negative or a special print does not appear to be any advantage, and it is satisfactory to learn that the process is not dependent upon purely mechanical operations, but is to some extent a matter of skill. This discovery by M. Chassagne is of great scientific interest, but its development and the particulars of procedure are for the present matters concealed carefully from the public because of the commercial issues involved. It will be important to the medical profession when the discovery becomes patent, since its application to the photography of sections and specimens in surgery and in anatomy should prove of great value.

TYPHUS FEVER AT PEKIN.

THE lately issued volume of the Medical Reports of the Imperial Maritime Customs, China, reviewed in our columns last week, contains a notable contribution to the literature of typhus fever by Dr. Matignon, of the French Legation at Pekin. Considering the hygienic conditions obtaining in that city and the north of China generally, it is not surprising that typhus fever should be endemic and that every year in the spring it should become epidemic. The mortality from it is considerable, but not so great as that from cholera. The European colony is mostly exempt, but the disease is liable to attack the missionaries and members of religious fraternities, who are brought more in contact

Digitized by Google

with the people than are members of Legation and others. It is mainly upon his observations of cases amongst such communities that occurred in the spring of 1895 that Dr. Matignon has based his studies. His essay gives an excellent account of the characteristics of the malady, together with detailed notes of cases, and it is interesting to find that there were certain notable differences observed between the disease as there shown and the form familiar to Europe. In the first place, the incubation period was much shorter than generally admitted—instead of being about twelve days he found that it seldom exceeded four or five days, and was often not more than twenty-four hours. The onset was abrupt and the fever high from the first, with headache, pyrexial pains, congested face, but less marked prostration than usual. About the fifth day the rash appeared, and, contrary to the exanthem as we see it, was most irregular in its evolution, often taking a week for its full development, and then being profusely scattered over the whole body. The rash had the characters of the rose spots of typhoid fever, and in hardly a single instance did it become petechial, nor was the skin so markedly mottled as it is in the European fever. As regards the type of pyrexia and the date of crisis there does not seem to have been any departure from the western malady but in many of the symptoms there were curious differences. Thus there was seldom seen the intense prostration or depressed aspect so characteristic of typhus fever as we know it. Headache, however, was most severe, and articular pains were a striking feature throughout the attack. Sleep was disturbed; delirium was variable—sometimes somnolence and sometimes a peculiar state of amentia. Deafness was constant and there might be amblyopia. It was noticed that there was a marked tendency to diarrhœa rather than constipation, but one of the most characteristic and serious conditions was the degree in which the heart became affected, the pulse being remarkably quickened and the cardiac second sound reduplicated. Apparently there was not such intense pulmonary congestion as is often met with, nor was albuminuria nearly so frequent. Convalescence was often prolonged, and retarded by abscesses, boils, or, as in three cases related by Dr. Matignon, by more serious sequels, as gangrene of the skin, osteo-myelitis, and periostitis. He observed one case of relapse and also one of second attack, both of which occurrences are rarely met with in Europe. The memoir is one which, from the careful and thorough manner in which Dr. Matignon has studied the clinical characters of the disease, deserves the attention of writers on the subject.

HER MAJESTY THE QUEEN has been graciously pleased to accept a copy of "The Life and Times of Thomas Wakley."

HER MAJESTY THE QUEEN, the Patron of the Order of St. John of Jerusalem, has approved the admissions of Sir Joseph Fayrer, Bart., K.C.S.I., M.D., Hon. Physician to the Queen and H.R.H. the Prince of Wales, Mr. William Fairbank, M.R.C.S. Eng., surgeon to Her Majesty's Household at Windsor and Surgeon in Ordinary to T.R.H. Prince and Princess Christian of Schleswig-Holstein, and of Mr. Norman Hay Forbes, F.R.C.S. Edin., as Knights of Grace of the Order.

THE medical staff and lecturers of the Dental Hospital of London have issued invitations to a conversazione at the Galleries of the Royal Society of British Artists, Suffolk-street, on Tuesday next, July 20th. The prizes for the year will be distributed by Sir Frank Lockwood, Q.C., M.P., at 8.30 P.M.

AFTER the annual dinner of the Hospital Reform Association, which is to take place on the 26th prox., there will be a discussion on Hospital Abuse, more especially with reference to the nature of the remedies that should be adopted. The discussion will be initiated by Dr. Isambard Owen, and Mr. C. S. Loch and others will take part in it.

M. HENRI DUNANT, of Geneva, whose name is well-known in connexion with the foundation of the "Red Cross Society," and who is now unfortunately in very reduced circumstances, has been granted a pension of a thousand roubles annually by the Russian branch of the society.

H.R.H. THE MARCHIONESS OF LORNE and the Marquis of Lorne have kindly promised to open the Passmore Edwards' Convalescent Home for the Metropolitan Hospital at Cranbrook, Kent, on Tuesday next, July 20th, at 4.30 P.M.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

VISIT OF T.R.H. THE DUKE AND DUCHESS OF YORK TO THE BANK OF ENGLAND.

ON Friday, July 9th, soon after 1 P.M., T.R.H. the Duke and Duchess of York visited the Bank of England to witness the destruction of the plates from which the stamps issued for the benefit of the Prince of Wales's Hospital Fund were printed. It will no doubt be remembered that as soon as the printing of the stamps was completed the plates were consigned to the strong rooms of the Bank of England under the official seals of the Governor and chief cashier, which were affixed in the presence of several of the honorary officials of the Fund, until a convenient opportunity presented itself for their destruction. At this function H.R.H. the Duke of York, who, as President of the London Philatelic Society, takes a great interest in the matter, graciously signified his willingness to be present.

Their Royal Highnesses, who were attended by Sir Charles Cust and Lady Mary Lygon, on arrival at the entrance in Lothbury, were received by the Governor, Mr. Hugh Colin Smith; the deputy governor, Mr. S. Steuart Gladstone; the chief cashier, Mr. H. G. Bowen; and the acting secretary, Mr. Kenneth Grahame; and also by the following members of the Organising Committee of the Prince of Wales's Hospital Fund: Lord Rothschild, Lord Rowton, Sir Henry Burdett, the Right Hon. C. Stuart Wortley, Q.C., M.P., Sir Savile Crossley, and Mr. J. G. Craggs.

There were also present Mr. J. S. Purcell, C.B., Controller of Stamps at Somerset House; Mr. Thomas de la Rue of Messrs. de la Rue and Co. who carried out the printing of the stamps and who so kindly prepared the design, engraved the plates, and presented them to the Fund free of charge; Mr. G. H. Miles and Mr. Joseph Shaylor of Messrs. Simpkin, Marshall, and Co. the wholesale distributors of the stamps, whose task in dealing with the issue has been anything but a light one; Mr. S. G. Wilkinson of the Oxford Bible Warehouse who have used a very large number of the stamps in their Commemoration Bibles and Prayer-books; and representatives of the various philatelic societies.

The Royal party were at once conducted to the printing department, which they entered by a private passage through the branch bank's office, and where they were met by Mr. W. J. Coe, the superintendent of the department. Passing through the machine-room, where all the account-books of the bank are printed—and where, by the way, is the first machine from which the postal orders were printed, and also a fine Middleton Gripper machine which prints both sides of the paper at once—the Royal party reached the die-sinking department, where the destruction of the plates was to take place. In this room, which is under the charge of Mr. F. C. Smith (who has been in the service of the bank over forty years), all the dies and water-marking plates are designed and made for the bank-notes, postal orders, Indian notes, Exchequer Bills, and any other papers requiring a water-mark; and Mr. Smith takes a pride in showing a paper mould (from which the water-mark is impressed upon the

Digitized by Google

paper whilst in course of manufacture) of a fine Damascus pattern, the process for making which was patented by his father (Mr. John Smith) in 1849, the mould being shown at the Great Exhibition of 1851.

At the benches in this room were stationed in readiness three expert workmen, each provided with an enormous two-inch file or rubber weighing sixteen pounds, and as soon as the seals of the plates, which had previously been brought from the strong rooms under the charge of the bank officials, had been broken by the Governor, the steel plates were fixed in position on the benches and the workmen set to work with a will to obliterate every line of the delicate tracery constituting the design of the plates. With the powerful tools at hand even the hard surface of the three steel plates from which alone the stamps have been printed soon had to yield, and after about ten minutes or a quarter of an hour's hard work the surface of the plates was utterly defaced. The destruction of the steel plates being complete, the attention of the workmen was then directed to the original matrix and die, the raised surface of the designs upon which, being too hard to be much affected by the powerful files which had been used upon the printing plates, were then applied to a grindstone which stood ready at hand, and in a short space of time the designs were ground level with the surface of the matrix and die. The defaced plates and dies were once again consigned to the charge of the Bank officials.

Their Royal Highnesses then proceeded to the Governor's room, where the official certificate of the destruction of the plates was signed by the Duke and Duchess of York, Mr. H. C. Smith, the Governor of the Bank of England, Mr. J. S. Purcell, C.B., Controller of Stamps, and the following members of the Organising Committee of the Prince of Wales's Hospital Fund: Lord Rothschild, Lord Rowton, Sir Henry Burdett, the Right Hon. C. Stuart Wortley, Q.C., M.P., Sir Savile Crossley, and Mr. J. G. Craggs.

The certificate is as follows:—

"Bank of England.

"Certificate of the Destruction of the Dies and Plates employed in the Production of the Prince of Wales's Hospital Fund Stamps.

"We, the undersigned, hereby certify that the whole of the Dies and Plates used in the production of these Stamps were this day destroyed in our presence."

Here follow the signatures as above.

The Governor of the bank then said: On behalf of the Committee of the Prince of Wales's Fund I beg to thank your Royal Highness and the Duchess for coming here to-day to see the plates destroyed. Perhaps you will kindly certify to those present that you are quite satisfied that no more stamps can be printed from the plates.

The Duke of York replied: It has interested both the Duchess and myself a great deal to come to-day and see the destruction of the dies and plates of the stamps which are issued in connexion with the Prince of Wales's Hospital Fund, and I trust that the remainder of the stamps will be soon sold, as I think there can be no more appropriate souvenir of Her Majesty's Diamond Jubilee than these Stamps.

His Royal Highness added that the defaced plates and dies might form an interesting exhibit at the forthcoming Philatelic Exhibition which he is to open in London on the 22nd inst.

The Royal party afterwards made a tour of the printing department of the bank, where they were much interested in inspecting the details of producing the bank-notes, postal orders, cheques, &c.

THE VICTORIAN ERA EXHIBITION AT EARL'S COURT.

ON Monday members of the press were invited to a private view of the incubators for infants at the Victorian Era Exhibition, Earl's-court. These are exhibited in a building facing the Welcome Club, and divided into three compartments. On one side there is sleeping accommodation for two wet nurses and for Mdlle. Louise Recht, who has been specially trained at the Paris Maternity Hospital to look after debilitated and prematurely born infants reared in incubators. A separate service for this purpose was established at the *Maternité* in 1893, and here some 400 children, born under most unfavourable circumstances, are received annually. On the other side of the building there is a nursery, where the infants are taken to be fed and washed. The public are admitted to the central room, and here they can view the infants lying within the incubators, and are shown how the apparatus is ventilated and warmed and the temperature automatically maintained. The mechanism employed for this purpose has already been fully explained in these columns.[1] Its efficiency is now put to a practical test. Messrs. Coney and Schenhein, who are the representatives in England of this the "Altmann Incubator," invite the criticism of the medical profession, and will supply every possible facility for the fullest investigation. They are ready to take in their charge any prematurely born child, and, apart from the trained nurse and the wet nurses, they have retained the services of two physicians, who attend three or four times a day to watch over the health of the infants. At night the watchman awakes the nurses every three hours so that they may feed the infants, and in the day time the babies are fed, generally from the breast, every two hours. In the nursery there is a small pharmacy, contrivances for sterilising milk, ingenious feeding bottles, and scales so that the infants may be weighed and their progress duly observed. A very large number of persons have already visited this exhibit, including many trained nurses. Much interest is manifested by the visitors. The incubators and the ventilating tubes are silvered, which gives them a bright and cheerful appearance, while the infants within look clean and comfortable, so that altogether it is a pleasant as well as an interesting sight.

It so happens that among the exhibits of the London Hospital to be seen in the main building there is an old-fashioned incubator which serves to illustrate the progress accomplished in modern days. This old incubator is not aseptic, for it is simply a wooden box with a glass lid, nor can the temperature within be automatically maintained. It is warmed by placing underneath three stone bottles containing hot water. Of course, the water becomes cold and the temperature falls unless the attendant is very careful. Nor is there any system for filtering and moistening the air. Instead of breathing pure outside air the infant must breathe the air of the ward or room in which he or she is placed. How all these inconveniences can be avoided will be made manifest to those persons who visit the special exhibit of the Altmann Incubators.

In other respects the exhibits of the London Hospital give a graphic object-lesson of the progress made in medicine, surgery, and nursing. Thus, while Messrs. Krohne and Sesemann show the improved and the new surgical instruments they supply to the London Hospital, there is displayed on a table the somewhat primitive instruments that were used at the hospital at the commencement of the century. Among the comparative novelties are the regulating inhalers for the administration of anæsthetics. Messrs. Krohne and Sesemann have also an improved patent lever spring for correcting the malposition of the great toe, and there is Largiader's apparatus for strengthening the chest and limbs, by which home gymnastics may be practised for the modest cost of 7*s.* 6*d.* Here, also, will be found Messrs. Allen and Hanburys' well-known pharmaceutical preparations, and their surgical instruments, their furniture for operating theatres, nurses' bags, pocket cases, and other things of interest to the profession, together with a patent portable bed-rest.

The London Hospital exhibits present to the public many of the most striking features of a surgical ward. For instance, there is one bed with a dummy figure representing a man who is supposed to be suffering from fever. From a cradle placed over the bed two large metallic trays are suspended containing ice. Rubber pipes travelling from these trays drain off the water to a bucket under the bed. Formerly a number of little buckets were tied to the cradle. These were more easily upset, and as they retained the water the bed was often wet. For the new beds now used the wire spring mattress is fastened to the iron framework and there is no wood whatsoever. But there are fracture boards that can be introduced to harden that portion of the bed where a spring mattress would interfere with the treatment of the patient. Further, all the heads of the beds can be easily lifted off whenever it is necessary to administer anæsthetics. There is also an ingenious method for lifting

[1] THE LANCET, May 7th, 1897.

Digitized by Google

off the side of a cot, and it slides down a groove perpendicularly to the floor, so that it takes up no room. Then there is a new table on high legs, which passes over the beds, and can be wheeled up to the patient without resting on the bed clothes. The application of a cradle for fractured tibia is shown on a dummy figure, as also the methods employed for hip extension and the operation of tracheotomy. Among the curiosities, the old operating table used a century ago at the London Hospital and Miss Nightingale's carriage which she employed in the Crimea evoke much interest.

In this section the Jubilee Institute for Nurses have their exhibit. They display the bags they carry about with them, and their various ingenious contrivances for extemporising, in the dwellings of the poor, whatever may be required for the successful nursing of the sick. What changes can be thus brought about are illustrated by pictures of the interiors of houses, notably of Irish huts, before and after the nurse's visit.

The Metropolitan Asylums Board, the St. John Ambulance Association, the Army Medical Department, and Messrs. Burroughs and Wellcome (outfits for field purposes) have extensive exhibits in another part of the building. The education department was, from the sanitary point of view, a decided disappointment. We did not, for instance, notice the plan or the photograph of a single schoolroom provided with lateral light or any scientific method of warming and ventilating. There were, however, several pictures of class-rooms where these modern improvements and sanitary principles are utterly ignored. The careful treatment of milk and all its products by the London and Provincial Dairy Company was much more satisfactory. Here fresh milk, strawberries and cream, ices, &c., may be enjoyed by the visitor while contemplating cows and calves contentedly chewing the cud in model stables.

Altogether, though the Victorian Era Exhibition is in the main a pleasure resort, still there are some exhibits of technical interest to members of the profession, so that a small portion at least of the time devoted to a visit may be usefully as well as agreeably employed.

METROPOLITAN HOSPITAL SUNDAY FUND.

WE continue below our record of some of the principal amounts received at the Mansion House, the lists of which have been forwarded to THE LANCET office. The total sum now amounts to £31,000 :—

	£	s.	d.
St. Jude, South Kensington	566	19	5
Church of the Annunciation, St. Marylebone	217	15	9
St. Andrew, Stoke Newington	73	14	8
St. Andrew (Presbyterian), Upper Norwood	53	2	0
Regent-square Presbyterian Church	99	3	8
"F" (a further)	50	0	0

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6790 births and 3192 deaths were registered during the week ending July 10th. The annual rate of mortality in these towns, which had declined from 15·8 to 14·7 per 1000 in the three preceding weeks, rose again last week to 15·1. In London the rate was 15·1 per 1000, and almost corresponded with the mean rate in the thirty-two provincial towns, which was 15·2 per 1000. The lowest rates in these towns were 7·3 in Croydon, 8·7 in Huddersfield, 8·8 in Swansea, and 9·3 in West Ham; the highest rates were 20·0 in Liverpool, 20·6 in Burnley, 21·3 in Salford, and 23·1 in Preston. The 3192 deaths included 504 which were referred to the principal zymotic diseases, against 404 and 409 in the two preceding weeks; of these, 170 resulted from diarrhœa, 143 from measles, 75 from whooping-cough, 59 from diphtheria, 33 from scarlet fever, and 24 from "fever" (principally enteric). The lowest death-rates from these diseases were recorded in Bradford, Bristol, Derby, Huddersfield, and Halifax; while they caused the highest rates in Wolverhampton, Birkenhead, Burnley, and Preston. The greatest mortality from measles occurred in Bolton,

Digitized by Google

Manchester, Birkenhead, Salford, Burnley, and Preston; from whooping-cough in Burnley, Oldham, and Norwich; and from diarrhœa in Birkenhead, Preston, Liverpool, and Leicester. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 59 deaths from diphtheria included 43 in London, 4 in Burnley, 2 in Portsmouth, and 2 in Liverpool. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns, and no cases of this disease were under treatment in the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2885, against numbers increasing from 2380 to 2821 at the end of the ten preceding weeks; 349 new cases were admitted during the week, against 274, 267, and 310 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 142 and 127 in the two preceding weeks, further declined to 116 last week, and were 76 below the corrected average. The causes of 41, or 1 3 per cent., of the deaths in the thirty-towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Leicester, Bradford, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Salford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·4 and 18 7 per 1000 in the two preceding weeks, further declined to 17·7 during the week ending July 10th, but was 2·6 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·7 in Greenock and 14·3 in Aberdeen, to 22·1 in Leith and 22·6 in Dundee. The 529 deaths in these towns included 28 which were referred to diarrhœa, 20 to whooping-cough, 17 to measles, 10 to "fever," and 7 to scarlet fever. In all, 82 deaths resulted from these principal zymotic diseases, against 69 and 77 in the two preceding weeks. These 82 deaths were equal to an annual rate of 2·8 per 1000, which was 0·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The 28 fatal cases of diarrhœa showed a further increase upon recent weekly numbers, and included 19 in Glasgow and 4 in Edinburgh. The deaths referred to whooping-cough, which had been 16 and 21 in the two preceding weeks, were 20 last week, of which 6 occurred in Glasgow, and 5 in Leith. The 17 fatal cases of measles slightly exceeded the number recorded in the preceding week, and included 9 in Edinburgh and 6 in Leith. The 10 deaths referred to different forms of "fever," corresponded with the number in the preceding week, and included 5 in Glasgow and 3 in Dundee. Of the 7 fatal cases of scarlet fever 4 were recorded in Edinburgh and 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 104 and 86 in the two preceding weeks, further declined to 69 last week, and were 15 below the number in the corresponding period of last year. The causes of 25, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·8 and 20·3 per 1000 in the two preceding weeks, rose again to 21·6 during the week ending July 10th. During the thirteen weeks of last quarter the death-rate in the city averaged 27·3 per 1000, the rate during the same period being 15·5 in London and 24·9 in Edinburgh. The 145 deaths registered in Dublin during the week under notice showed an increase of 9 upon the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 11 in each of the two preceding weeks; of these, 2 resulted from diphtheria, 2 from whooping-cough, 2 from "fever," 2 from diarrhœa, and 1 from scarlet fever. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 2·5 in London and 3·7 in Edinburgh. The fatal cases of diphtheria, which had been 5 and 4 in the two preceding weeks, further declined to 2 last week. The mortality from scarlet fever also showed a decline, while that from whooping-cough showed an increase. The 2 deaths from diarrhœa corresponded with the number recorded in the preceding week. The 145 deaths in Dublin last week included 28 of infants under one year of age, and 31 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded those recorded in the preceding week. Four inquest cases and 4 deaths from violence were registered; and 51, or more than a third, of the deaths occurred in public institutions. The causes of 7, or nearly 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JUNE, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during June in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·7 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 7·8, 7·2, and 8·1 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Hammersmith, St. George Hanover-square, Westminster, Hampstead, Stoke Newington, St. Martin-in-the-Fields, and Lewisham; while they showed the largest excess in Holborn, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, St. Saviour Southwark, and Battersea. Four cases of small-pox were notified in London during June, against 8, 11, and 10 in the three preceding months; of these, 2 belonged to Battersea, 1 to Bethnal-green, and 1 to the Port of London sanitary areas. No small-pox patients were admitted into the Metropolitan Asylum Hospitals during June, and none remained under treatment at the end of the month. The prevalence of scarlet fever in London showed a further increase upon that recorded in recent months; this disease was proportionally most prevalent in Strand, Clerkenwell, Whitechapel, St. George-in-the-East, Mile End Old Town, St. Saviour Southwark, Battersea, and Lee sanitary areas. The Metropolitan Asylum Hospitals contained 2786 scarlet fever patients at the end of June, against 2468, 2330, and 2495 at the end of the three preceding months; the weekly admissions averaged 272, against 208, 225, and 258 in the three preceding months. The prevalence of diphtheria in London showed a slight further increase upon that recorded in the two preceding months; among the various sanitary areas this disease showed the highest proportional prevalence in Holborn, St. Luke, Whitechapel, St. George-in-the-East, Mile End Old Town, St. Saviour Southwark, and Camberwell. There were 864 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of June, against 776, 764, and 783 at the end of the three preceding months; the weekly admissions averaged 125, against 127 and 108 in the two preceding months. The prevalence of enteric fever in London also showed a further slight increase upon that recorded in the two preceding months; this disease was proportionally most prevalent in Clerkenwell, Poplar, St. Saviour Southwark, and Newington sanitary areas. Erysipelas showed the highest proportional prevalence in Marylebone, St. Giles, Bethnal Green, St. Saviour Southwark, and Rotherhithe sanitary areas. The 24 cases of puerperal fever notified during June included 3 in Lambeth, and 2 each in Fulham, St. Pancras, Islington, St. George-in-the-East, Limehouse, and Camberwell sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, July 3rd, the deaths of 5953 persons belonging to London were registered, equal to an annual rate of 13·9 per 1000, against 17·4, 16·6, and 14·9 in the three preceding months. The lowest death-rates during June in the various sanitary areas were 8·6 in Stoke Newington, 9·2 in Lewisham (excluding Penge), 9·7 in Strand, 9·9 in Plumstead, 10·8 in Hampstead, and 11·0 in Paddington; the highest rates were 19 2 in St. Saviour Southwark, 19·3 in St. George Southwark, 21·0 in City of London, 21·3 in St. George-in-the-East, 22·1 in Limehouse, and 26·3 in St. Luke. During the five weeks of June 624 deaths were referred to the principal zymotic diseases in London; of these,

156 resulted from diphtheria, 141 from whooping-cough, 131 from measles, 101 from diarrhœa, 64 from scarlet fever, 28 from enteric fever, 2 from ill-defined forms of continued fever, and 1 from small-pox. These 624 deaths were equal to an annual rate of 1·5 per 1000. No death from any of these zymotic diseases occurred during June in St. James Westminster, St. Martin-in-the-Fields, or Strand sanitary areas; among the other sanitary areas the lowest zymotic rates were recorded in St. Giles, St. Saviour Southwark, Lee, and Plumstead; and the highest rates in Clerkenwell, St. Luke, Shoreditch, St. George-in-the-East, Limehouse, and Rotherhithe. The single fatal case of small-pox belonged to Clerkenwell sanitary area. The 131 deaths from measles were little more than a third of the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Clerkenwell, St. Luke, Limehouse, Mile End Old Town, and Rotherhithe sanitary areas. The 64 fatal cases of scarlet fever were 25 below the corrected average number; the mortality from this disease was highest in Rotherhithe sanitary area. The 156 deaths from diphtheria were 14 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Holborn, Clerkenwell, Shoreditch, St. George-in-the-East, and Limehouse. The 141 fatal cases of whooping-cough were 99 below the corrected average number; the mortality from this disease was highest in St. Pancras, Shoreditch, Limehouse, Poplar, St. George Southwark, and Newington sanitary areas. The 28 deaths referred to enteric fever were 13 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 101 fatal cases of diarrhœa were little more than half the corrected average number. In conclusion, it may be stated that the mortality in London during June from these principal zymotic diseases was nearly 46 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 109 per 1000 during June, and was considerably below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Paddington, Stoke Newington, Strand, St. Olave Southwark, Greenwich, Lee, and Plumstead; and the highest rates in Hammersmith, St. George Hanover-square, Holborn, City of London, St. George-in-the-East, St. George Southwark, and Rotherhithe.

THE SERVICES.

ARMY MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL J. H. MOORE has been appointed to officiate on the Administrative Medical Staff of the Army, with the temporary rank of Surgeon-Colonel, vice Surgeon-Colonel C. A. Atkins, on leave. Surgeon-Major R. D. Hodson has been posted to Sheerness for duty. Surgeon-Captain L. Way has been posted to the Station Hospital, Canterbury, for duty. Surgeon-Major S. C. B. Robinson has proceeded from York to Leeds for duty, in relief of Surgeon-Major J. R. Dodd, who proceeded to Woolwich for duty as Senior Medical Officer at the Royal Arsenal. Surgeon-Captain R. A. Bostock, Scots Guards, has been selected for promotion to the rank of Surgeon-Major in the Grenadier Guards, in succession to Surgeon-Lieutenant-Colonel W. Campbell, 1st Battalion, retired.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain R. W. H. Jackson, M.D., A.M.S., are replaced at the disposal of the Military Department. Ernest Whitmore Newton Guinness, gent., to be Surgeon-Lieutenant, East Indian Railway Volunteer Rifles, vice Whitaker, resigned. Surgeon-Lieutenant-Colonel H. Johnstone, Rangoon Volunteer Rifles, Brigade-Surgeon-Lieutenant-Colonel, Indian Medical Service, resigns his commission. The Volunteer Officers' Decoration has been conferred upon Surgeon-Lieutenant-Colonel Thomas Holbein Hendley, C.I.E., 2nd Battalion Bombay, Baroda, and Central India Railway Volunteer Rifles, Brigade-Surgeon-Lieutenant-Colonel Indian Medical Service. Surgeon-Lieutenant-Colonel J. M. Zorab, Civil Surgeon of Bhagalpur, is appointed to be Civil Surgeon of Cuttack, vice Brigade-Surgeon-Lieutenant-Colonel C. J. W. Meadows, retired. Surgeon-Captain J. T. Calvert, Civil Surgeon of Mymensingh, is appointed to be Civil Surgeon of Bhagalpur, vice Surgeon-Lieutenant-Colonel J. M. Zorab, but will continue to act as Inspecting Officer for the purpose of carrying out the provisions of the Epidemic Diseases Act, 1897, at Khana Junction, East Indian Railway, until further orders. Surgeon-Captain C. E. Sunder, Officiating Civil Surgeon of Rangpur, is appointed to act as Civil Surgeon of Bhagalpur during the absence on deputation of Surgeon-Captain J. T. Calvert, or until further orders. Surgeon-Major C. P. Lukis, from the Rohilkhand Volunteer Rifles, to be Surgeon-Major, to complete the establishment. The following appointment is made on the Personal Staff of the Governor of Bombay:—Surgeon-Captain J. B. Jameson, M.B., C.M., 28th Pioneers, to act as Medical Officer during the absence of Surgeon-Major H. Martin, M.B., on leave.

VOLUNTEER CORPS.

Artillery: 1st Sussex (Eastern Division, Royal Artillery): Surgeon-Major W. S. Burrows to be Surgeon-Lieutenant-Colonel. 1st Midlothian: Surgeon-Lieutenant W. B. Macdonald, M.B., to be Surgeon-Captain. 4th Lancashire: William McClelland, M.B., to be Surgeon-Lieutenant. The Highland: Surgeon-Lieutenant G. Geddes, M.B., resigns his commission. *Rifle:* 1st Volunteer Battalion the Suffolk Regiment: Surgeon-Captain M. E. Ling to be Surgeon-Major. 5th Volunteer Battalion the South Wales Borderers: John Robert Isaac Raywood, gent., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the York and Lancaster Regiment: Surgeon-Captain Charles Carter Moxon resigns his commission, and is appointed Second Lieutenant. 1st Volunteer Battalion the Highland Light Infantry: Surgeon-Captain N. Stark, M.B., resigns his commission. 1st Dumbartonshire: Charles Frederick Spinks, gent., to be Surgeon-Lieutenant.

CONTAGIOUS DISEASES IN INDIA.

Reuter's correspondent at Bombay telegraphing on July 13th says: "The new rules under the Cantonments Bill are published to-day. They apply equally to all contagious diseases, and require that doctors and house-owners shall give information respecting any outbreak of such diseases. Objections to the rules will be considered up to Aug. 10th."

THE FRENCH ARMY MEDICAL SERVICE.

In 1882 the strength of the medical department was fixed at 1300 of all ranks — viz., 1 inspector-general, 9 inspectors, 45 principal medical officers of the 1st Class, 45 principal medical officers of the 2nd Class, 320 surgeon-majors of the 1st Class, 480 surgeon-majors of the 2nd Class, 300 assistant-surgeon-majors of the 1st Class, and 100 assistant-surgeon-majors of the 2nd Class. In addition to the foregoing 60 probationers from Val-de-Grâce were also to be made available for duty. During the decade and a half that has elapsed many changes have taken place in all the other cadres of the active army, the total numbers in each case having been largely increased, but the *Service de Santé* remains *in statu quo*, marking time while all the other sections are advancing. In 1893 M. Mézières, in the name of the army commission, recommended the creation of eighty-one new posts in order that the department might be able to answer requirements in time of peace, and serve as leaven in time of war to the 5000 or 6000 medical officers of the reserve and territorial forces; but the Minister of War proposed a compromise, being willing to grant forty new appointments only, and in the end nothing was done. Owing to the system of training up youths in special institutions there is no lack of candidates for the French army medical department, but apparently among the officers in general discontent is widespread. They consider themselves unfairly handicapped by the authorities, and in support of their complaint point to the German army, whose *Corps de Santé* numbers 1800 in all, or 500 in excess of their own strength.

The Hampshire Company of the Militia Medical Staff Corps arrived at the Royal Victoria Hospital, Netley, on July 3rd to undergo its annual training. The Company is under the command of Surgeon-Captain W. M. O'Connor, M.B. Surgeon-Captain O'Connor is attached to the Medical Division, and Surgeon-Lieutenant H. E. Mortis, Militia Medical Staff Corps, to the Surgical Division. The total strength of the Company is sixty-four officers and men of all ranks.

At the quarterly meeting of the directors of the Naval

Mézières, in the name of the army commission, recommended the creation of eighty-one new posts in order that the department might be able to answer requirements in time of peace, and serve as leaven in time of war to the 5000 or 6000 medical officers of the reserve and territorial forces; but the Minister of War proposed a compromise, being willing to grant forty new appointments only, and in the end nothing was done. Owing to the system of training up youths in special institutions there is no lack of candidates for the French army medical department, but apparently among the officers in general discontent is widespread. They consider themselves unfairly handicapped by the authorities, and in support of their complaint point to the German army, whose *Corps de Santé* numbers 1800 in all, or 500 in excess of their own strength.

The Hampshire Company of the Militia Medical Staff Corps arrived at the Royal Victoria Hospital, Netley, on July 3rd to undergo its annual training. The Company is under the command of Surgeon-Captain W. M. O'Connor, M.B. Surgeon-Captain O'Connor is attached to the Medical Division, and Surgeon-Lieutenant H. E. Mortis, Militia Medical Staff Corps, to the Surgical Division. The total strength of the Company is sixty-four officers and men of all ranks.

At the quarterly meeting of the directors of the Naval

Medical Supplemental Fund, held on July 13th, Inspector-General W. H. Lloyd in the chair, the sum of £61 was distributed among the several applicants.

Correspondence.

"Audi alteram partem."

"THE RECENT PRIMARY FELLOWSHIP EXAMINATION AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—I would like to sound the note of harmony amidst the clash of argument between "A Surgeon of Thirty Years' Standing" and "Anatomist." "Anatomist" focuses his reply on the somewhat unfortunate "German flute" metaphor. But even this is right in substance. And he quotes only such parts of the questions on the terminal portion of the rectum, the topography of the liver, the thyroid gland, &c., as he thinks support his view. These questions bear a different complexion when looked up in the Calendar. They include an account of the development of the organs mentioned, this involving, especially in the case of the liver, about the most intricate questions in embryology. One cannot describe intelligently the development of the liver without fixing the site of its first formation, which means tracing the separation of the pleural and peritoneal cavities. And similarly with the questions as to the nasal septum and the broad ligament of the uterus, to which are added riders as to the vestigial structures connected with these parts, with a reference, in the case of the broad ligament, to their homologues in the male sex.—"But it would never do at the higher examination to ask simply the topography of the liver," someone might say; "everybody would answer that."—"Tack on the partition of the cœlom and the formation of the mediastina."—"Or the three last inches of the rectum."—"Include the closure of the early cloaca and the differentiation of the sexes." We have in these additions the true explanation of the deficiency of the candidates as to "simple accurate knowledge of ordinary general anatomy," of their failing, of all subjects, on the bones. But then the men have been giving all their time to getting up the small type in the new editions of the text-books, and know next to nothing of the anatomy and physiology "without which a sound knowledge of the profession is impossible."

Generalities are not telling in argument. Let us narrow the point to assuredly familiar matter.—"Kindly put out your tongue."—"Would you mind telling me what for? what have you *seen*, who charge for looking down my throat, of the structures beneath the fur on the surface?" Fortunately patients do not often thus address us. But, honestly, what should we answer if they did? Are there not many of us nowadays who know little or nothing, in the true and practical sense of knowing, in the old surgeon's sense of knowing, in the sense of having personally dissected them, of the structures—as Inquisitive puts it—beneath the fur on the surface? I ask the question seriously, in the inner circle of "*nos intimes*," and in the light of your leading articles on Jan. 20th, 1894, and Feb. 6th of this Jubilee year. "*Numbers who dissect ..... dwindling to a minimum.*" "*Dissections of the deeper parts seldom made now*"—*ergo*, tongue, larynx, pharynx, soft palate, rectum, liver, and broad ligaments taught by "a system of chalks, blackboards, and tutorial cramming classes."

But then the corresponding higher examinations become examinations of a higher standard only in regard to the "high falutin'" matter now being introduced and examinations of a lower standard in regard to the anatomy and physiology already defined, in "Anatomist's" words, as that "without which a sound knowledge of one's profession is impossible." In those examinations in which a separate "honours' set" of questions are issued are there not a good many who pass, and aim at passing, on the "honours' set," who know that they would fail on the ordinary, or "pass set"? No less an authority than Professor Struthers "distrusts the honours' list." But then the "honours' list," for professional purposes, becomes—a possible list of dishonour. The new school dissects but little. It explains, and tries to get men to "understand"—that is, to imagine. In saying this, I fear I am calling down a chorus of denials on my head. But I stick to my point. It is true that things are not so *in principle*. *In principle* the new school insists strongly on practical work of all kind. "One part dissected with care," writes Professor Macalister, "is worth a dozen hurried over." Indeed, the zeal and personal example of the leaders are admirable. But the field of work is so enormously extended by the superadded "transcendentalism," that theory and practice cannot go hand in hand. The highest aspirations notwithstanding, the fact is as above stated. And this is by no means limited to work for the higher examinations. It extends to everything. The present system, the "cram" system, is demoralising the schools, discrediting the examining bodies, and dishonouring the profession.

The above is on the surface, and everyone can see it. But let me cross-examine "Anatomist" in regard to something more recondite, as to which he is right, but without quite understanding how, as to something which underlies and shapes the intellectual groundwork on which we stand, and, indeed, explains the apparently inexplicable. How does "Anatomist" tally facts with the view as to the same kind of knowledge being required (except as to greater (?) accuracy) for the higher as for the more ordinary examinations, and as to the examiners not pressing questions requiring more than "very ordinary knowledge" till *after* the candidate has shown himself entitled to a pass? If this be so—and I maintain that it *is* so—how do questions as to vestiges and homolcgues, and the hardest and most unsettled questions in embryology find their way into the *papers?* Will "Anatomist" give the key? The examiners are not trying to pluck. They are simply endeavouring to do their duty; and, on the whole, doing it remarkably well. But why do they make the examinations so "ingeniously eliminative"? They do nothing of the kind—intentionally, at least. Why do they pluck "70 per cent. of the candidates—eighty of the most hard-working and intelligent students"? Because "70 per cent. of the candidates—eighty of the most hard-working and most intelligent students" do not know the "attachment of muscles," the "position of the bones," and the like. We have this on the authority of the examiners' present mouthpiece, "Anatomist."

I maintain that the fault does not lie, in the main, with the examiners. With whom does it lie? With the teachers? Neither—in regard at least to their honestly doing their best by their men. Then where does the evil come from? It comes from the conditions under which both teachers and examiners are working. It comes from the conditions created by the text-books. It comes from the specialists, who, in writing them, pile up detail upon detail, until they make each part of a science a science in itself. Would that I could discourse here on a few of the pointed sayings of the inimitable Mr. Mitchell Banks, or on a few of the weighty apothegms—"Go to nature," for example—of our much endeared Professor Struthers. But I have done this elsewhere, and your space is precious.

Let us "Go to nature." The examiners are not unreasonable. They are tied down somewhat, or think they are—too much so, perhaps; but it is only a passing craze. They do not lay much stress on the transcendental. They do not know much about it themselves. How could they? They are, in the main, surgeons. Show them a little knowledge of Nature. Handle your bones. Look at your muscles. Dissect your large vessels and nerves. Dip your hands into the cavities. Let your knowledge be true knowledge, and not the "information poured upon the memory" (Struthers); and trust to the honour of those who are but a little ahead of you. The examiner soon distinguishes between your book knowledge, rattled off perhaps in unimpeachable phraseology, and your true knowledge, presented, perhaps, in terms laboured and inappropriate, but at least in your own English. One candidate answers "A 1," who probably knows "no more of his subject than he does of Greek." Another answers "well, as a youngster can when necessarily hauled over questions that would puzzle the Presidents of our Colleges." It is to the standing honour of the examiners that they usually pluck the first candidate and pass the second. No body of men are doing their work better, on the whole, than the College examiners. Examinations are easy enough to pass, with just a little honest,

Digitized by Google

practical work, resulting in a little, simple, plain, true knowledge. "Anatomist" is right here. But the men do not know it. Tell them that they are running after the unattainable and valueless, and missing the good things at their door. Tell them, and thus solve the problem of the 70 per cent. of plucks.

I am, Sirs, yours faithfully,

THOMAS COOKE, F.R.C.S.

July 12th, 1897.

THE GARRULOUS THERMOMETER.

To the Editors of THE LANCET.

SIRS,—Your annotation in THE LANCET of June 26th on the case recorded in the *Indian Lancet* draws attention to a wonderful case of high temperature that to me seems inexplicable. I should like to notice, however, one sentence bearing on what may be considered an abuse of the thermometer. The annotation says: "For weeks the temperature was taken every quarter of an hour, as the rise was often very sudden." The wonder to me is that the woman survived these repeated experiments.

Undoubtedly the clinical thermometer is a great aid in the diagnosis of many diseases. *Per contra*, it is a most mischievous little instrument in the fingers of a fussy nurse, who looks upon it as a sort of fetich to be used on all possible occasions, very often to the discomfort or even detriment of the helpless patient. Montgomery, of Dublin, formerly preached strongly against the evils of meddlesome midwifery, and a warning note might prudently be rung out to-day against the too frequent use of these instruments of precision, especially in the hands of the ignorant. In cases of acute pneumonia, rheumatic fever, &c., where rest is a prime factor in recovery, the meddlesome application of the thermometer for some minutes is a small premium on death, and how often this is done as mere routine needlessly and hurtfully I know full well.

In one case, a young man who had passed through a severe attack of acute rheumatism with heart complications at the age of sixteen years, during his convalescence unfortunately heard that should he have a recurrence and the temperature reach 104° it would go hard with him. This patient had a recrudescence of an alarming nature at twenty-two years of age, and was nearly killed by the fiat of two medical men, who, with grave shake of head, croaked out in his hearing, "Yes, very ill indeed. Temperature 104°." Fortunately I had an instrument that would not register over 100°, and a sight of this was "good medicine" to the otherwise helpless man. Had this man succumbed I should always have considered that the road to death was shortened—it certainly would not have been smoothed—by the reading of the thermometer and the wisdom that it evoked.

Fear is a grave disease, and the unwarrantable use of these appliances, especially in certain temperaments, is accountable for much mischief. Were it not that I have read the sensible advice to "boil it down" much might be written on this subject of some import. My object in this brief letter is simply to draw attention to the mis-directed use of a valuable adjunct to our art, and to point out that this silent monitor in the hands of a garrulous person is capable of great misdoing. The *mens medica*, surely a gift more or less, is not sufficiently cultivated, whereas that dumb orator, the clinical thermometer, is not unfrequently accountable for the manufacture of high temperatures.

I am, Sirs, yours faithfully,

R. A. CALDWELL.

Beckford Lodge, Southampton, July 12th, 1897.

MERCER'S HOSPITAL, DUBLIN.

To the Editors of THE LANCET.

SIRS,—Kindly permit me to explain a statement appearing in THE LANCET of July 10th, which I assume was made by your Dublin correspondent, and might be wrongly interpreted by those not acquainted with the facts. The statement I refer to is that the only member of the old staff of Mercer's Hospital who had been re-elected was Dr. Ward. This might imply that the old staff had sought re-election at the hands of those who purported to have dismissed the entire medical and surgical staff of the institution, and which act was done without alleging any cause whatsoever. A resolution was passed by a section of the board to the effect that for the purpose of regaining for the old institution the high position it formerly held, and to increase the public confidence in the management of the hospital, it was resolved to call upon all the medical and surgical staff to resign with a view of appointing a new staff, and that *the old staff would be eligible for re-election.* It is needless for me to point out the absurdly contradictory nature of this resolution; for if it was necessary to dismiss the medical staff to regain a name for the institution it would be absurd to re-elect those whose names were associated with any deterioration. Subsequently it was decided by the board that all who did not send in their resignations should stand dismissed. So far as applying again to the board who passed such a resolution, condemning, without reason, the entire staff, I think I am safe in saying that no one save Dr. Ward applied for re-election.

Not only did I myself not apply for re-election, but I deny the power of the board to dismiss the staff without cause. It is significant that the time selected by the board for their high-handed act is the beginning of the legal long vacation, when the matter cannot be heard for months; but it is my intention, so soon as the circumstances of the case will allow, and so far as law will permit, to have the matter decided in the interests of the medical profession, my colleagues, and myself.

I am, Sirs, yours faithfully,

EL. STAMER O'GRADY,

Senior Surgeon to Mercer's Hospital.

Merrion-square, Dublin, July 13th, 1897.

THE HALF-YEARLY MEETING OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—The value of these meetings becomes much diminished if a small meeting maintains a quorum merely to accept and register the decision of the Council, and the adverse vote of a large meeting is met by a plebiscite on an unfair basis, as was the case with that of the meeting of Fellows which accepted the principle of extending the franchise to the Members. Until this plebiscite the Fellows had shown considerable independence of thought and action. Where were these at the last meeting or in the course adopted by the Association of Fellows at the recent election? Only one Fellow seemed to retain them, for on the amendment being carried and put as a substantive motion Mr. Anderson and Mr. Jackson, the mover and seconder of the original motion, did not vote, and yet one Fellow voted consistently. The meaning of By-law XV., which provides for the rights of Fellows and Members—and in the next motion the principle of representation on which the whole profession is governed were under consideration. Yet of thirty Fellows present besides the mover and seconder only the President of the College touched these subjects, and he explicitly stated that he did not speak on behalf of the Council. He did not give a single reason why the by-law does not apply in Mr. Anderson's case, but only deplored the idea of its being put in operation as derogatory to a scientific body. If it were derogatory it might be no less binding. If it is not binding the reason should be stated by the Council. If it be binding it is not consistent with the honour of the Council to repudiate its engagements. The explanation as to Mr. Bryant's position (I speak impersonally) is, though still unofficial, no more satisfactory. There can be no true representation unless the representative is responsible to those he represents; and if the representatives of the bodies corporate on the General Medical Council have no responsibilities to those who appoint them, then twenty such free agents—a majority of the General Medical Council—constitute an arbitrary and irresponsible government controlling the whole medical profession. The failure of the Fellows present to rise to the level of the occasion, the tameness with which they resigned their important functions in favour of an absolute discretion in the Council, should be matter of grave reflection to the rest of the body corporate, and especially to the Members of the College. Disused functions are quickly lost. If, as has lately appeared, the Fellows do not intend to claim any control over the affairs of the College it is time action was taken to prevent the Council from achieving the absolute supremacy it asserts.

Digitized by Google

Sir Robert Craven's suggestion that Mr. Anderson's wrongs are suitable matter for appeal to the whole profession met with the favour of the meeting and the commendation of the chair; but appeals to the whole profession on suitable subjects should, it would appear, be led by the leaders of the profession; and why not by the great professional corporations, including the greatest, which is the College?

I am, Sirs, your obedient servant,

July 14th. A FELLOW OF THE COLLEGE.

THE INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.

To the Editors of THE LANCET.

SIRS,—May I call attention to certain matters concerning the approaching International Medical Congress at Moscow?

Firstly, there is need for clear instructions as to how to send money to Russia. Postal orders payable in Russia are not issued in England. English banks will not supply drafts on Russian banks for sums of less than £10. Bank-notes are not allowed to be sent through the post in Russia. Money can be sent by English cheque crossed "Crédit Lyonnais"; but then the rate of exchange seems hard to ascertain. One friend of mine sent a cheque for £1, which he thought was equivalent to 25 francs, or 20 marks, or 10 roubles, but he only got a receipt for 8 roubles 50.

Secondly, the Moscow managers of the Congress seem what we in England should call dilatory. Another friend of mine sent his subscription a month ago, but has had neither receipt nor card of membership. I believe that no one in England has yet had a card of membership. The preparations that have to be made before travelling in Russia as to passport and railway ticket will make inconvenience result if the issue of cards of membership is postponed till the last moment.

Perhaps the ventilation of these matters may lead to closer attention to the convenience of intending members. I enclose my card. I am, Sirs, yours faithfully,

July 14th, 1897. F R.C.P.

*** The form of inscription says that a cheque of the value of 25 francs or 20 marks (10 roubles) may be sent, and in most cases we believe that a cheque for £1 has been followed by a receipt on a post-card stating that the sender will be enrolled as a member of the Congress. In cases where the amount credited has been 3 roubles 50 we believe that the sender will be inscribed. Of a credit for a less sum in response to a cheque for £1 we have had no examples brought to our notice previously. The official instructions are not explicit, and our advice is that all intending members should send a cheque for one guinea direct to the secretary-general, Professor W. K. Roth. The cards of membership ought to be issued, and we hope that the delay in sending them will not be extended. We would remind those who are expecting them that they must indicate to the secretary-general their place of arrival on the frontier.—ED. L.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.

(FROM OUR BERLIN CORRESPONDENT.)

(*Concluded from p. 57.*)

The Use of the x Rays in Internal Medicine.

PROFESSOR BENEDIKT (Vienna) said that the x rays were an important addition to our methods of cardiac diagnosis. The size of the heart, which formerly could not be precisely ascertained when the organ was covered by the lungs, as in emphysema, is now easily measured; arterio-sclerosis can also be recognised in an early stage, and the formation of aneurysms may be observed. The rays are also valuable in studying the respiratory system, for not only do they enable the action of the diaphragm to be ascertained in health and disease, but infiltration of the pulmonary apices and the formation of cavities become visible, and foreign bodies in the thorax may be detected by the same means. The examination of the abdominal organs by the rays had, however, not yet proved very successful.—In the course of the discussion Dr. Levy-Dorn and Dr. Rosenfeld showed skiagraphs of aneurysms, and Dr. Becher recommended that Esmarch's artificial anæmia should be employed when the extremities are being examined, for the outline of the bones is thereby rendered more apparent.

The Use of Drugs in Modern Medical Practice.

Professor Liebreich (Berlin), the well-known adversary of bacteriology and serum treatment, said that the discovery of many powerful remedies was due to the systematic practical trial of a variety of substances—in fact, to the empiric method of inquiry, entirely without the assistance of theoretical considerations. Digitalis and iodine were notable examples of drugs which had been introduced into medical practice in this way. The recent great advances in synthetical chemistry have resulted in the formation of a host of compounds the properties of which remain for pharmacologists to investigate. Physicians may think that they are overwhelmed by the number of these new substances which are pressed on their notice; they ought, however, not to complain, but rather to welcome such extended opportunities of selection, whereby they are enabled to choose drugs appropriate to individual cases. There are remedies, such as quinine and mercury, which are specifics, inasmuch as they are directly antagonistic to the morbid process or cause of illness, but the mode of their action is as yet far from being known. Since the discovery of bacteria medical men have carefully studied the substances which are capable of destroying them, but in this connexion it is essential to take the cellular elements of the organism equally into consideration, and to avoid the error of concentrating attention exclusively on the micro-organisms, for it often happens that the bacteria associated with a given illness are not the primary cause of it, but have merely been developed to an unusual extent in consequence of the vital energies of the tissues becoming lowered from some cause or other. The bacillus of tubercle, for instance, is to be found in the lungs of healthy persons, and its development assumes the character of a pathological process only after the vitality of the pulmonary cells has been impaired. The treatment of pulmonary tuberculosis ought, therefore, to aim, not at the destruction of the bacilli, but at the restoration of the vital energy of the pulmonary cells. For this reason nourishing food and attention to hygiene are essential; cantharidin has also proved useful. The bacteriologists are of opinion that diseases ought to be classified according to the bacteria which are associated with them. Would they, however, give the name of "coli-bacillosis" to cases of arsenical poisoning in which the bacterium coli was discovered in the heart of animals? and would they try to destroy the bacteria in preference to endeavouring to get rid of the poison? Professor Liebreich was of opinion that Professor Koch's new anti-tuberculin would not be more successful than the former preparation. With regard to Behring's diphtheria antitoxin, he said that the mortality from diphtheria is reported to have diminished since the introduction of the treatment, but competent observers like Kassowitz, of Vienna, and Rose, of Berlin, admit that they have not seen any good effect resulting from it. The history of diphtheria prevalence also shows that periods of low mortality have occasionally occurred. In conclusion, Professor Liebreich asserted that tetanus antitoxin was useless, and that the practical results of the new serum treatment had by no means come up to the expectations to which it gave rise.—A very animated discussion followed Professor Liebreich's address.—Professor Baginsky claimed that the good results of the serum treatment were undeniable.—Professor Behring, after remarking that Kassowitz published his observations five years ago, offered to provide Professor Liebreich with a supply of toxins and antitoxins with which he could himself perform any experiments he might think desirable.—Professor Liebreich, in his reply, said that he did not question the statement that mixtures of toxins and antitoxins made in a test tube were inert.

The Treatment of Chronic Diseases of the Heart.

Dr. Rumpf (Hamburg) said that in the dietetic prescriptions given to patients suffering from chronic heart disease only albumin, fat, and carbohydrates had been hitherto taken into consideration. He has made experiments concerning the action of salts of lime in the organism, and has found (1) that when too much of these salts is present in the food a good deal of it becomes retained in the body; (2) that in calcification of the arteries the elimination of the lime-salts decreases; and (3) that the amount of the lime salts in

Digitized by Google

blood is very inconstant. A decrease of lime salts in the food must thus be of therapeutical value. Dr. Rumpf has investigated the influence of several substances on the elimination of lime salts, and has found that hydrochloric acid, lactic acid, and organic salts of potassium promote it, whilst phosphoric acid had no influence; experiments with oxalic acid and salicylic acid are in progress. As to the amount of albumin necessary for the organism, Dr. Rumpf believed that from sixty to eighty grammes were sufficient. He also recommended food containing a large quantity of potassium and sodium salts such as vegetables and fruit, and expressed his opinion that a mixed dietary was preferable to one consisting exclusively of meat and fat.

Puncture of the Spinal Canal.

Dr. Lenhartz (Hamburg) has performed this operation in grave cases of chlorosis where the increased pressure of the cerebral fluid caused violent headaches. In 10 cases out of 20 operated on the pains disappeared at once. The principal indication for the operation is cerebro-spinal meningitis. He has resorted to puncture in 46 cases of tuberculous and 24 cases of idiopathic cerebro-spinal meningitis In the first group the tubercle bacillus was found in 21 cases only. Of the second group, in 13 cases Weichselbaum's, and in 9 Fränkel's, diplococcus was present; in one instance the bacillus of enteric fever was discovered, and in one instance no bacillus at all could be detected. Dr. Lenhartz was of opinion that it was still uncertain whether the bacillus intercellularis was the cause of epidemic cerebro-spinal meningitis; all his cases were sporadic and were not sufficiently numerous to found an opinion on.—Professor Fürbringer (Berlin) has performed the operation in a new series of 26 cases of tuberculous meningitis, in 14 of which the tubercle bacillus was found. He had previously published a series of 37 cases, in 30 of which the bacillus was present. He had also found the method very useful for the recognition of cerebro-spinal meningitis, and has succeeded in diagnosing cerebral hæmorrhage in 10 cases by its means. In one instance, where it was doubtful whether the patient suffered from delirium tremens or from fracture of the skull, the hæmorrhagic fluid obtained by puncture proved the existence of a traumatic lesion.

Acute Leukæmia.

Professor Fränkel (Berlin) said that a characteristic symptom of acute leukæmia was the hæmorrhagic diathesis in conjunction with swelling of the glands, the liver, and the spleen. He has seen 12 cases within seven years. A good many of them were erroneously believed to be purpura hæmorrhagica, but a correct diagnosis could always be made by a microscopical examination of the blood. The increase of mononuclear leucocytes is very characteristic. Professor Fränkel terms them lymphocytes, and the whole morbid process lymphocythæmia. He has once observed a peripheral paralysis of the facial nerve due to an immigration of leucocytes into the substance of the nerve. In the same case the enormous quantity of twelve grammes of uric acid were discharged within forty-one hours.

Iodine in Disorders of the Circulation.

Professor Vierordt (Heidelberg) said that he had been giving iodine to patients suffering from disorders of the circulation when the usual dietetic and mechanical treatment had not succeeded in relieving the pains. Cases of arterio-sclerosis were especially suitable for this treatment, but it was not applicable to patients over sixty years of age suffering from cardiac debility and albuminuria. At first from 0·25 to 0·5 gramme of iodide of sodium as given several times, so that from 1½ to 3 grammes were taken in the course of a day; afterwards iodide of potassium was administered. It is essential that the patients should use the iodine for a somewhat long time—say, nine months in the first year. After an interval of from three to six months the administration of iodine was resumed. The remedy was very well borne; sometimes, however, the digestion was interfered with. The treatment was remarkably successful, especially in the cases of six patients who had suffered from severe angina pectoris, but who improved so much that they were able to ascend hills and also to return to business. With regard to the theoretical explanation of the action of iodine he was of opinion that the lesion was prevented from extending, but was not actually repaired. It has been suggested by Sée, Huchard, and others that an effect is produced on the vaso-motor nerves, but this is not probable.

Fatty Degeneration.

Dr. Rosenfeld (Breslau) said that the alleged difference between fatty degeneration and fat infiltration was based upon the hypothesis of a metamorphosis of the cellular albumin into fat. He has examined the pathological conditions where this metamorphosis is believed principally to occur, especially in the livers of animals poisoned by phosphorus and phloridzin. In starving dogs to which phloridzin had been administered a quantity of fat was stored in the cells of the liver. This fat did not proceed from the albumin of the cells, as the albuminous substances were not decreased. When mutton fat was injected into the cellular tissue of the skin poisoning by phloridzin made the mutton fat pass from the skin into the liver. In phosphorus poisoning also the fat only passed from the cellular tissue into the liver; this fact was very obvious in starving dogs where the fat had entirely disappeared. In these animals poisoning by phosphorus was not able to produce fatty degeneration of the liver. An artificial injection of mutton fat makes this fat again appear in the liver. Dr. Rosenfeld concluded his address by the remarkable statement that fat is never formed from albumin and that the theory of fatty degeneration must thus be abandoned. When the albuminous substances of a cell are destroyed the loss is supplied by fat passing into the cell. The fat of the organism consists exclusively either of that which is taken as food or that which is formed from carbohydrates.

An abstract of all the papers read before the Congress would occupy more space than can be spared. The principal ones, next after those already enumerated, were as follows: Professor Kronecker, on Death by Thrombosis of the Coronary Arteries; Dr. Friedländer, on Alterations of the Blood by Thermic Influence; Professor Hochhaus, on Experimental Myelitis; Professor Goldscheider, on the Neuronic Theory; and Professor von Mering, on the Function of the Stomach. The next congress will be held in Wiesbaden.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Pressure of Lunacy Admissions at the Liverpool Workhouse.

THE pressure occasioned by the number of lunatics admitted to the Liverpool Workhouse last month was so great that it became necessary to notify the police that for the present the workhouse authorities were unable to receive any more lunatics brought to the workhouse by them. In order to find accommodation for lunatics ten epileptics had to be transferred from their proper wards to the wards occupied by ordinary inmates. The vestry clerk pointed out that every board of guardians in Lancashire is in a similar position as are, to a large extent, others throughout the country. The Lunacy Board are making arrangements, and are now building for something like 1000 patients near Warrington. The clerk was instructed by the Select Vestry to write to the Local Government Board and the Commissioners in Lunacy, and to point out to them the serious state of affairs prevailing in this district. The Commissioners in Lunacy, in their reply, intimated that they could not help the Select Vestry in the matter, as the responsibility rested with the Lancashire County Council and the Lancashire Asylums Board. The reply from the Local Government Board was not encouraging. Altogether matters are in a very unsatisfactory state, all the other unions in this neighbourhood being in similar straits.

Bequest to the Medical Faculty of University College, Liverpool.

By the will of Mrs. Gee, widow of the late Dr. Robert Gee, formerly lecturer in the diseases of children in the Medical School, a sum of £7000 has been bequeathed to the Medical Faculty of University College, Liverpool, for the promotion of study and research in medical science. It was decided by the Medical Faculty to institute a Robert Gee Fellowship in Anatomy of the value of £100 for one year; also four entrance scholarships of the value of £25 each for one year. The late Dr. Gee was also a generous donor to the Liverpool Medical Institution, of which he had been treasurer and president.

The Lyon-Jones Scholarships

The Senior Lyon-Jones Scholarship, open to all second

Digitized by Google

year's students of the medical faculty who have completed two years of study at University College, has been awarded to Mr. W. J. Young. The Junior Lyon-Jones Scholarship, open to all candidates who have passed any of the preliminary examinations accepted by the Victoria University for the Medical degree course, has been obtained by Mr. D. M. Alexander. Each scholarship is of the annual value of £21, and is tenable for two years.

Resignation of Dr. H. C. Chapman.

Dr. H. C. Chapman, the medical superintendent of the Mill-road Infirmary, has felt it imperative to resign his appointment, owing to ill-health. He has been connected with the Mill-road Infirmary for about twelve years, during which period he so gained the full confidence and respect of the West Derby guardians that they have now granted him the highest superannuation permissible. Dr. Chapman intends to proceed to South Africa without delay, where, it is hoped, his health may improve. The intelligence of his ill-health and intended departure from Liverpool came as a surprise to his numerous friends, with whom he was deservedly popular.

Hospital Extension.

The City Council approved of the recommendation of the Port Sanitary and Hospitals Committee that the sum of £3000 should be placed at the disposal of the committee for the purpose of extending and completing the additions and improvements to the Netherfield-road infectious hospital and the furnishing thereof.

Stanley Hospital.

The committee of this institution at their last board meeting decided to open sixteen of the beds remaining closed for want of funds. Early in the year they issued an appeal to the public for the purposes of liquidating the debt of £2229 and opening the whole of the beds, but the responses have not been sufficient to justify the committee undertaking so heavy an expenditure.

July 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Changes at the Royal Infirmary, Edinburgh.

Two of the surgeons to the Royal Infirmary—namely, Dr. John Duncan and Mr. A. G. Miller—have just completed their full term of office and retire from the active staff. Mr. Cotterill has been appointed a full surgeon and Mr. Cathcart has been placed in charge of the surgical wards reserved for the women students, while Mr. Caird takes Mr. Cotterill's place in the lock wards. Mr. Harold Stiles has been appointed to the vacancy on the staff of assistant surgeons. This appointment has given great satisfaction. On the medical side the vacancy in the staff of assistant physicians has been filled by the affirmation of the appointment of Dr. R. F. C. Leith. The vacancy in the pathological department is to be filled next week and there are several applicants for the post.

The Meeting of the British Medical Association in Edinburgh.

Arrangements have already been begun on the understanding that this association will hold its annual meeting in Edinburgh in 1898. A large meeting of the profession was held in the Royal College of Physicians of Edinburgh on Monday, at which a committee of selection was appointed. Treasurers were instructed to appeal for funds, and the appointment of secretaries was made. Sir Thomas Grainger Stewart is nominated as President.

The Close of the Summer Session, Edinburgh.

The summer classes in the Medical Faculty close this week and arrangements are being made for the holiday season. Professor Cossar Ewart delivers the address to the medical graduates on one of the last days of the present month, instead of on the first lawful day of August, as under the old law which has been modified to this extent by the new ordinances.

Infectious Hospital at Aboyne.

A curious dispute has occurred as to the infectious diseases hospital which the district committee of the county council had commenced to erect at Aboyne. Sir W. C. Brooks, Bart., of Glen Tana, apprehensive of the effect of the presence of such an establishment in a summer resort such as Aboyne, has offered to pay £1000 if the hospital be removed to a site at Dess about a mile and a half from the village of Aboyne. It may be mentioned as a significant fact in connexion with matters of this kind that the Aberdeen City Hospital for Infectious Diseases, which was originally in the country, has now been surrounded by dwelling-houses without any known cases of communication of infection.

Presentation to a Medical Man.

Dr. William Reid, medical superintendent of the Aberdeen Royal Lunatic Asylum, was presented on the 9th inst., by his board of directors, his official colleagues in every branch of the institution, and a few intimate friends with a handsome silver tea and coffee service, on the occasion of his approaching marriage with a daughter of Dr. Bruce of Dingwall.

Examiners at Aberdeen University.

The University Court of the University of Aberdeen, at its meeting on the 13th instant, appointed as additional examiners, each for a period of four years from Feb. 1st, 1898, the following—viz.: Anatomy: Arthur Keith, M.D. Aberd., of the London Hospital Medical College, London. Physiology: M. S. Pembrey, M.A., M.D. Oxon., of Charing-cross Hospital Medical School, London.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Dublin.

THERE has recently been a very great improvement in the condition of Dublin as regards health. For the week ending July 3rd, Sir Charles Cameron stated the death-rate at 20 per 1000 persons living, the mean-rate for the corresponding week of the last ten years being 27·3. Belfast also shows a remarkably clean bill of health, the rate being 14·8. The Cork rate was 23·5; Kingstown seems to be especially healthy this season, the deaths being only at the rate of 5·6 per 1000. At a meeting of the Dublin Sanitary Association on July 9th, it was remarked that four deaths from diphtheria had taken place during the week which ended on the previous Saturday.

Beri-beri at the Richmond Asylum.

At a meeting of the governors of this asylum, which took place on the 13th, the medical superintendent, Mr. Conolly Norman, reported a recent outbreak of beri-beri in the institution. During the last fortnight fifteen new cases had occurred, twelve female patients and three nurses having been attacked. In reply to Mr. Clancy, Mr. Norman stated that there had been at one time as many as seventy persons suffering from the disease. It became worse during the summer, attained its height in the autumn, and passed away in the winter and spring. It had never, however, been entirely absent for the last three and a half years. Other instances of congestion in lunatic asylums have recently been reported, for instance, at Armagh, Londonderry, and Monaghan, but no case of beri-beri has appeared. The governors of the Londonderry Asylum have recommended that immediate steps be taken to erect buildings capable of meeting the requirements of sixty additional patients. At the Monaghan Asylum the medical superintendent reported recently that there were 137 patients over the proper number in the house.

Ulster Medical Society.

At the annual meeting of the Ulster Medical Society, held on July 9th, the council's report showed that the society was in a very flourishing condition, while financially the treasurer has a good balance in his hands. The following office-bearers were elected for session 1897-98: President, Dr. J. A. Lindsay; Vice-Presidents, Professor W. H. Thompson and Dr. McKisack; secretary, Dr. Colville; treasurer, Dr. John McCaw; librarian, Dr. Shaw; pathological secretaries, Dr. J. Lorrain Smith and Dr. Lynass; council, Dr. Campbell, Dr. Calwell, Dr. Bingham, Dr. Kevin, Professor Byers, and Dr. Gaussen.

Presentation of Addresses to Mr. John Fagan.

Mr. John Fagan, F.R.C.S. Irel., who was recently appointed inspector of industrial schools in Ireland, has been the recipient of two very flattering addresses from his medical friends in Belfast. One of the addresses was from his old colleagues, the members of the staff of the Royal Hospital, where for over twenty years Mr. Fagan was a surgeon and where he was greatly respected by his *confrères*

Digitized by Google

both as a friend and as a skilful operator. This address was presented to Mr. Fagan on July 8th, on the occasion of an extremely social and pleasant dinner given in his honour by Dr. Walton Browne, senior surgeon to the Royal Hospital, and at which nearly all the staff of the hospital were present. The second address was presented to Mr. Fagan on July 9th from the members of the Ulster Medical Society, of which he was twice president. Mr. Fagan was also elected an honorary member of the society, and most flattering speeches were made at the meeting by several of the members, expressive of their admiration for Mr. Fagan and of the loss the medical profession in Belfast had sustained by his removal to another sphere of duty. Mr. Fagan goes to Dublin, carrying with him the best wishes for his happiness and prosperity.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Academy of Medicine.

M. LANNELONGUE has read before this society a long paper dealing with his method of treating hernia by the injection of chloride of zinc under the skin. He showed some cases from which a better judgment could be formed than when he first introduced this method about a year ago. Preparatory treatment is unnecessary, and the only point to be taken into consideration is to compute the renal adequacy of the patient according to the method of Ahard. Care must be taken not to wound the spermatic cord or to throw the injection into the peritoneal cavity. At the moment of operation an assistant places his finger in the abdominal ring, and the operator injects from ten to twelve drops of the solution of chloride of zinc, taking care to press a finger on the cord. The first injections are made at the level of the external abdominal ring at the upper border of the pubes at first internal to, and then external to, the cord. The operation does not last more than two or three minutes. After the operation nothing is needed but a spica bandage. No anæsthetic is necessary, but to obtain quiet, children may be given a little chloral, and if they are over three years of age a little morphia may be added. The chloride of zinc brings about a necrosis of the tissues, together with an enormous immigration of leucocytes. Frequently enough fibrous and fatty tissue form to completely block up the canal. M. Lannelongue has employed this method in fifty-one cases. Between the ages of one and twenty years he had forty-four cases, forty-one of whom were permanently cured, two incompletely cured, and one was a failure. Two subjects of between fifty and sixty years of age had large double hernias; one case failed and the other was a success. Two women with simple hernias were completely cured.

Another Scandal at a Maternity Clinic.

The lay press recently made a great to do about the case of a pregnant woman who, accompanied by her husband, presented herself at a maternity hospital and was referred to the central office of the Assistance Publique as there was no vacant bed. The Assistance Publique, however, referred the woman to another hospital, saying that they did not take in lying-in cases. So the woman stopped in the street while her husband was being referred from one department of the administration to another, and while this was going on she was suddenly delivered in the street of twins. The chief secretary of the Prefecture of Police happened to be passing at the moment and gave orders for a conveyance to take the mother and children to a hospital. The daily press is much exercised over this matter, which could easily have been avoided had someone telephoned to the maternity hospital first of all to inquire if there was a bed. They forget, however, that women only too often put off till the last moment attending the hospital and are frequently confined in the carriage on the way there. The Prefecture of Police has been compelled to make policemen undergo a very elementary course of midwifery, for cases of women being confined on their way to the hospital are becoming so very common.

The New Tinea Hospital.

At the Hospital of St. Lois there has just been opened a new ward for the reception, treatment, and education of children suffering from tinea and allied conditions. Attached to this ward is a school, to which has been given the name of the École Lailler, and here the children will continue their studies without interruption during the long course of treatment necessary. Formerly when a child was attacked with tinea no school would take the patient, and he or she was therefore condemned to a long term of enforced idleness; but this new school will allow of these unfortunate little ones continuing their studies and being treated at the same time. The new building, which is divided into spacious class-rooms, well lighted and ventilated, will accommodate 650 pupils. The first division of the school is intended for cases of tinea tonsurans and contains 192 beds, and in its eight classes contains 418 children equally divided among out- and in-patients. The second division has 63 beds and school places for 200 children. A general infirmary with 28 beds will receive the sick from both these divisions. Altogether the Lallier School will contain 220 resident pupils, including the girls who come from the Trousseau Hospital and the boys from the Children's Hospital. The new buildings comprise a magnificent laboratory and spacious dining-rooms, which after meals can be used in the winter as covered playgrounds. The dormitories, too, are fitted up in the very latest fashion. The palace thus offered to these little scald-heads has cost 1,500,000 francs, of which sum 1,100,000 francs have been supplied from the funds of the *pari mutuel* and 400,000 francs by the town of Paris. It was commenced on June 1st, 1895, and finished on June 1st, 1897. For the opening ceremony, which was fixed coincidently with the distribution of prizes, an enormous tent was erected in the large courtyard, and here, attired in a uniform consisting of a blue blouse and trousers, the little ones, with their heads covered by a white handkerchief, were able to admire the magnificent buildings destined for their use.

An Original Petition.

The ward at the hospital of the Salpêtrière which is allotted to the use of the in-patients is so old and dilapidated as to be almost unfit for habitation. Moreover, it is infested by bugs, which during these hot nights make sleep impossible, and the in-patients have for a long time past been asking that their quarters should be rendered more comfortable, but the director of the hospital remained deaf to their complaint. They therefore collected in a bowl all the bugs which they were able to catch in a night and addressed them to M. Peyron, the Director of the Assistance Publique, with this inscription: "Collection made in our dormitory on the night of July 6th–7th, 1897." They further say that every morning they will send him a similar parcel, and so the management is at last impressed with the necessity of finding these in-patients more comfortable quarters.

July 13th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The New Tuberculin.

THE *Deutsche Medicinische Wochenschrift* has commenced the publication of a series of communications describing the experiences of leading hospital physicians with Professor Koch's new tuberculin. The first article is written on behalf of the department for diseases of the throat and chest of the Charité Hospital in Berlin by Dr. Bussenius, assistant physician to that hospital. The treatment was used for nineteen patients, twelve of whom suffered from laryngeal tuberculosis, two from pulmonary tuberculosis, four from lupus, and one from asthma. With fifteen of those patients the treatment was continued until it was considered that the full effect was produced, and it was accordingly stopped; in one case it had to be stopped on account of hæmoptysis occurring, and three patients are still undergoing the treatment. The number of injections was 314 for the first fifteen patients and twenty-four for the last four cases; the quantity of fluid injected was 125·46 c.c., containing 1254·6 milligrammes of solid substance, its price being no less than 1066 marks (£53). The largest number of injections performed in one patient was twenty-five, and the greatest quantity injected was 15 c.c. The duration of the treatment varied from twenty-nine to sixty-five days. When the treatment was finished injections of the old tuberculin were made, with the result that none of the patients showed a reaction. In accordance with the recommendations of Professor Koch, the injections were begun with very small quantities and were therefore somewhat

Digitized by Google

quickly increased, Professor Koch believing that reaction may be avoided in this way. Dr. Bussenius found that the maximum dose was reached without febrile reaction in only four cases, whilst in the others the temperature generally rose after the injections. He stated that the fluid purchased from the Hoechst factory seemed to vary in strength. For instance, the preparation issued on June 4th caused not only fever, but also other and undesirable symptoms, such as swelling of the lymphatic glands, debility, &c., but bacteriological examination nevertheless showed it to be sterile; the preparation sent out on June 11th caused fever, which was ushered in by a rigor and lasted about twenty hours, the patient's temperature being 41·3° C. (= 106·3°F.). In one of the cases of lupus the injection of 1 c.c. of this tuberculin caused a swelling of the diseased cutaneous tissues similar to that observed with the old tuberculin. It was remarkable that the same patient had formerly received 4 c.c. from another bottle without any reaction. This result showed that the technical details of the preparation of the tuberculin still need improvement in order that the product may be always uniform. Great precautions are still necessary when a fresh bottle is used, the activity of which is not yet ascertained. The pulse and the respirations became more frequent simultaneously with the rise of temperature; two patients complained of oppression and excessive perspiration; disturbances of the digestion were never observed, and the appetite was not obviously influenced. In seven patients an increase in weight was observed and in five a decrease, whilst in two it was not changed at all. None of the 334 injections was followed by suppuration, but in some instances there was an infiltration round the place of the injection, which passed off without treatment. As to the effect of the treatment on the local process, it was stated that in two cases of pulmonary tuberculosis complicated by syphilis the cough and excretion where tubercle bacilli were present very soon disappeared; in laryngeal and pharyngeal tuberculosis there was no obvious amelioration in any instance. The local reaction was very slight, and there was no danger of laryngeal œdema, so frequent with the old tuberculin. The best results were obtained in cases of lupus. Two of the patients suffering from this disease recovered completely, seven and nine weeks respectively after the beginning of the treatment. In one case the healing went on very well and the greatest part of the lupoid area was in a state of cicatrisation; but the injection, unfortunately, had to be stopped owing to the above described troubles due to excessive energy of the tuberculin. The fourth case of lupus is still in an early stage of the treatment. Dr. Bussenius is not yet disposed to give a definite opinion as to the efficacy of the new tuberculin, but the results attained seem to fall short of the expectations of Professor Koch.—Another short communication on the new remedy is made by Professor Schultze, of Bonn, who has treated nine patients up to the present. The reactions so characteristic of the old tuberculin were never observed. In one case a laryngeal affection, probably of a tuberculous nature, made its appearance during the treatment, and the patient consequently refused to have the injections continued. Another patient suffered from diarrhœa after the injections, lost two kilogrammes (4½ lb.) in weight and declined further treatment. In four cases there was no apparent alteration of the patient's general condition, in one case of pleurisy there was a general improvement, and in two other cases a marked amelioration of the laryngeal affection was observed. Professor Schultze said that it was quite impossible to determine whether the amelioration was due to the treatment or to the general hygiene and dietetic measures.—This series of articles on the new tuberculin will be continued in the forthcoming number of the *Deutsche Medicinische Wochenschrift*.

July 12th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Heat and an Ice Famine.

THE above is a bad combination of which all who have to stick to their posts in Italian cities are "feelingly persuaded." The calorific wave that swept over the peninsula and islands recently, and has not yet spent its force, seems destined to take rank with the "Calori Storici" of the century, particularly those of 1861, 1881, and 1892. Already the superintendents of the various observatories throughout the kingdom are issuing comparative statistics of the "hot years," from which it results that 1897, with its temperature of 109° F. at Arezzo and at Sassari (Island of Sardinia), and its 95° F. at Brescia in the Alta Italia, is on the fair way to earn its *titolo di priorità*. Apart, however, from figures and their attempted explanation, seismic or meteorological, the heat this summer has been productive of unusual suffering and loss, of which we are but beginning to realise the extent. To aggravate the situation we are beset with an ice famine, sorely felt in all the great centres, particularly Rome, Florence, and Milan. Last winter, it will be remembered, was in Italy a remarkably mild one, in consequence of which the yield of ice was exceptionally poor. With an improvidence, however, which amounts, I fear, to a national characteristic, none of these cities was at pains to lay in a store against the inevitable requirements of the summer. In the last days of June and the first days of July the heat (as the poet says) "leapt upon us like a tiger." Central Italy was the first to wince under the shock. In Florence the butchers, the fishmongers, the poulterers, the dairymen, and the confectioners all found their wares becoming tainted and their business suspended. Under pressure of clamorous customers they besieged the ice-vendors' stores but were met with a "*non possumus*" which they interpreted as an excuse to raise the price of the commodity. In their exasperation they broke into the said stores, only to find "no effects" and a series of distasteful attentions on the part of the police. Now I hear they have had to telegraph for ice from the Mont Cénis, and the cost of the article from being 1 franc 20 centimes the hundredweight (*quintale*) is now 6 francs! Great as are the discomfort and sense of privation among the general public, it is in the hospitals where the ice famine is most felt, insomuch that the death-rate, particularly after surgical operations and among the admissions to the fever wards, must inevitably rise. It may be asked, Where are the artificial ice companies? That, however, has never been a flourishing manufacture in Italy, as may be inferred from the fact that of the 800 *quintali* consumed in Milan every year only 120 are artificial, the remainder (the natural ice) coming from firms in relation with Alpine sources. Neither Rome nor Florence, however, is so near the snow fields as the Lombard capital, and though the former has her Rocca Priora on the Alban Hills and the latter her Apennines, still, as I have said, the mild winter of 1896–7 in these quarters minimised the yield of ice and left the dealers without excuse for neglecting to replace it artificially or from the Alta Italia. In the well-nigh tropical summer of 1881 a similar "carestía del Ghiáccio" (ice famine) was equally felt, but improvidence and short memories go together, and it seems a special function of Italy to furnish object-lessons in both.

Water-carts and Street "Cultures."

Opinion, professional as well as popular, is divided on the question as to whether or no the streets in our cities should be watered. Quite lately a distinguished occupant of a university chair (I think of pathological histology) delivered a lecture on the subject, and after quoting the conclusions of the Hamburg Commission appointed *ad hoc* during or immediately after the latest cholera epidemic in that port left the problem, as they did, unsolved. The recent experiments of Wittlin, proving that the water-cart is a fertile fosterer of bacteria, have made a profound impression in Italy, favouring as they do the "quieta non movere" principle so dear to Southern populations. Leave the dust, it is said, to undergo the beneficent action of solar light, the steady desiccation (that best of all disinfectants), and put up with its inconveniences. "Better to bear the dust we have than fly," &c. But no one who has passed a summer in Italy, with the great increase of vehicular traffic, will be impressed with this argument. Why not fix the bacteria on the roads rather than favour their lodgement through the air-passages in the system? True, the mud left in the wake of the water-cart is in itself a "culture," which, if allowed to dry, will simply let loose a more formidable cloud of bacteria than before. But the water-cart itself might be better managed. Its operations should begin at daybreak, and while the roadway is still damp the scavenger or the steam brush should follow. Never water the streets during the hottest hours of the day (as is habitually done in Italy), but at those periods when evaporation is less rapid. It is all a question of more gradual and better-timed watering

Digitized by Google

(say the less unscientific among the disputants), calculated to succeed (they add) in a country where wood pavements with their organic detritus are as yet unknown.

Honours for Professor Sanarelli.

Besides conferring on the discoverer of the bacillus icteroides the honorary citizenship of Uruguay, the Montevidean legislature, in acknowledgement of his services, has voted him the donation of ten thousand pesos, at the same time recording its regret that "the unhappy condition of the country does not admit of its doing more to evince its gratitude to a physician and nature-student who has already laid those regions under so many obligations."

July 13th.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated :—

Monday, July 5th :

Anatomy and Physiology.—Thomas Sayers, Herbert Leach, and Edwin Samuel George Fowler, Yorkshire College, Leeds; Arthur Cardell Oliver, University College of South Wales, Cardiff; George Percy Smith, Lambert Arthur Wellesley Johnston, John Brentnall, Stanley, Vivian Hood Symons, and Bernard Septimus Hollick, Mason College, Birmingham; Alfred Ernest Underwood Hawkes, University College, Liverpool; Francis Bellairs Alderson and William Herbert Forshaw, Firth College, Sheffield; William Francis Harriott Coke, St. George's Hospital; Samuel Joseph Willcox, University College, Bristol; Oswald Lacey Addison, University College, London; Alfred Charles Stanley Waters, Cambridge University; Shapurji Hormusji Modi, Grant Medical College, Bombay, and St. Bartholomew's Hospital; Walter Brock Parsons and William John McCoy, Medical College, Madras.

Anatomy only.—Stanislaus Marcus Dowling, Catholic University of Ireland, Dublin and University College, Bristol; and John Ellington Jones, University College, Bristol.

Seventeen gentlemen were referred in both subjects, one in Anatomy only and two in Physiology only.

Tuesday, July 6th :

Anatomy and Physiology.—Robert Archer Lloyd, Alwyne Theodore Compton, Graham Shaw Arnold Smith-Wynne, Francis Williams Sheppard, Charles Saunder Chalk, Alfred Ernest John Lister, and Thomas Massey Pearce, St. Bartholomew's Hospital; Donald Poyntz Chapman, Charing-cross Hospital; Harold Cooper Pretty and Clifford Allchin Gill, University College, London; Edwyn Manners Ridge, Benjamin Charles Broomhall, Charles Robertson Porter and Edward Walter Bain, London Hospital; Burnet Graham Patch and Horace Georges Pinches, St. Thomas's Hospital; Sydney Greenwood Penny, St. George's Hospital; Arthur Falconer Hayden, St. Mary's Hospital; and Sydney John Peake, King's College, London.

Seventeen gentlemen were referred in both subjects.

Wednesday, July 7th :

Anatomy and Physiology.—Richard Robert Cruise, Erasmus Oakes Faulkener, Harry Tudor Newling, Reginald Ambrose Facey, and Cyril Evered Thwaites, St. Mary's Hospital; Frederic William Longhurst, St. George's Hospital; John Salmon Smith, Middlesex Hospital; Harold West Hodgson and Alfred Bertram Saltau, London Hospital; Basil Sorley Bartlett, Roger Lionel Hagger, and Geoffrey Allen Upcott-Gill, University College, London; Morgan James Rees and Frederick Goulburn Gibson, Guy's Hospital; John Evans Richards and William Monro Anderson, Charing-cross Hospital; Ernest Alfred Donaldson-Sim, St. Bartholomew's Hospital; John George Glasgow, St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology; and Clarence Herbert Downer, King's College, London.

Seventeen gentlemen were referred in both subjects.

Thursday, July 8th :

Anatomy and Physiology.—Thomas Percival Allen, William Christian Bumgarten Smith, Pascoe Bevil Grenfell, and Reginald Torriano Cooke, St Bartholomew's Hospital; Thomas Sidney Dawber Enderby, Eustace Raven, and Douglas Duke Turner, St. Thomas's Hospital; John Hamilton Hart, St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology; William Augustine Mc Enery, Middlesex Hospital; Ernest Vaughan Aylen and James Davey, London Hospital; Arthur Charles Duncan Newton and William Lawrence Steele, University College, London; Ashley West Talbot and Edgar Hall Felton, Guy's Hospital; Frederick Burroughs Jefferiss, King's College, London; William George Hopkins, St. Mary's Hospital; and Ernest Ronald Walker, Charing Cross Hospital.

Eighteen gentlemen were referred in both subjects.

Friday, July 9th :

Anatomy and Physiology.—Sydney Balch Green, Henry Cyril Adams, and Daniel Davies, St. Bartholomew's Hospital; Thomas Davidson Miller, St. Thomas's Hospital; James Ross Clemens, Jefferson College, Philadelphia, and St. Thomas' Hospital; Arthur St. John Bateman and William Lumsden Stuart, King's College, London; Edward Cecil Clements, Middlesex Hospital; Cecil Edward Last, St. George's Hospital; Patrick Dalgado, Grant Medical College, Bombay; Henry Somerville, Westminster Hospital; George Ernest Goode and Samuel Newall Foulkes, London Hospital; Thomas Copeland Savage, University College, London; and Thomas Shalden Smith, St. Mary's Hospital.

Anatomy only.—Herbert Charles, Middlesex Hospital; Leslie Frederick Enthoven, Cambridge University and Mr. Cooke's School of Anatomy and Physiology; and Thomas Langton Butler, St. Mary's Hospital.

Physiology only.—Elijah Richard Lockwood Thomas, London Hospital; and Fred. Algernon Simpson, St. Mary's Hospital and Mr. Cooke's School of Anatomy and Physiology.

Eleven gentlemen were referred in both subjects, four in Anatomy only and one in Physiology only.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentleman, having previously passed the necessary examinations and having now conformed to the by-laws and regulations, has been admitted a Member of the College :—

Donald John Armour, M.D. Toronto, Toronto University and University College Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—At the Primary Examination the following candidates passed in the subjects indicated :—

PART I.

Biology.—E. M. Forsyth, K. M. H. Hawkins, and T. G. Prosser, Royal Free Hospital.

Chemistry.—T. M. Burton, A. E. Gilford, C. Hind, H. M. Jones, and D. E. Lockwood, Royal Free Hospital; F. H. Maberly, Birmingham; L. S. Molony, F. M. Payne, and E. J. Polito, Royal Free Hospital; F. M. Rodgers, Manchester; and C. M. Scott, G. E. Soltau, and M. E. Unwin, Royal Free Hospital.

Materia Medica and Pharmacy.—J. Buckley, Manchester; H. H. Cotman, Aberdeen; E. A. Dunn, Royal Free Hospital; R. F. Ellery, St. Bartholomew's Hospital; W. J. H. Hepworth, Edinburgh; S. F. Hickman, Royal Free Hospital; W. Hunter, Durham; R. O. Jones and E. McD. Judge, Guy's Hospital; and J. A. Wolverson, Birmingham.

PART II.

Anatomy.—K. M. Betts, Royal Free Hospital; T. Burdekin, University College Hospital; C. E. C. Child, Charing-cross Hospital; H. H. Cotman, Aberdeen; T. B. Fawley, Leeds; K. E. Gregg, Royal Free Hospital; T. A. B. Harris, Sheffield; W. M. Hocken, Liverpool; T. E. Holman, Guy's Hospital; H. N. Horton, Middlesex Hospital; H. E. D. Lloyd, St. Bartholomew's Hospital; R. A. Lyster, Birmingham; H. MacMaster, Sydney and Edinburgh; D. V. Muller, Charing-cross Hospital; H. C. Pratt, Birmingham; M. E. Rocke, Royal Free Hospital; L. Sells, St. Thomas's Hospital; S. H. Smith, Royal Free Hospital; A. E. Whitehead, Sheffield; and W. R. Wilson, Dublin.

Physiology.—W. Asten, Birmingham; H. H. Beale, St. Mary's Hospital; J. R. Bentley, Cambridge and Middlesex Hospital; K. M. Betts, Royal Free Hospital; A. J. Blair, Belfast; A. F. Carlyon, Middlesex Hospital; A. Croneen, Guy's Hospital; A. M. Crosfield, Edinburgh; T. B. Fawley, Leeds; O. H. C. Fulton, Dunedin and Edinburgh; G. H. L. Hammerton and T. A. B. Harris, Sheffield; A. T. Harvey London Hospital; H. N. Horton, Middlesex Hospital; H. E. D. Lloyd, St. Bartholomew's Hospital; E. C. Pratt, Birmingham; M. E. Rocke, Royal Free Hospital; F. E. Shean, London Hospital; S. H. Smith, Royal Free Hospital; A. E. Whitehead, Sheffield; and J. H. Williams, London Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin :* The new Professor of Physiology, Professor Engelman, in taking over the late Dr. du Bois Reymond's chair, is arranging certain changes in the Physiological Institute and its four departments. The first, for microscopical and biological work, will remain under the charge of Professor Fritsch. Similarly, the second, for chemical physiology, will continue under its present director, Professor Thierfelder. The third, for special physiology, will be greatly enlarged, and the professor himself will take part in its work in conjunction with the present director, Dr. Immanuel Munk. The fourth department, for physical physiology, will also be largely increased; it will be called the Department for the Physiology of the Sensory Organs, and will remain under the direction of Professor König. In addition to extensive new buildings the supply of apparatus will be largely augmented. The lectures will be given by the professor in a course running through two semesters, but during the last four weeks in the summer Professor König will lecture on the sensory organs, and during the first four weeks of the winter Professor Thierfelder will lecture on physiological chemistry.—*Bologna :* Dr. L. Silvagni and Dr. F. Vitali have qualified as *privat-docenten* of medical pathology.—*Kazan :* Dr. Rustitaki has been promoted from Extraordinary Professor to Ordinary Professor of Operative Surgery.—*Kharkoff :* Dr. Podres has been promoted from Extraordinary Professor to Ordinary Professor of Surgery.—*Leipzig :* Dr. Kockel, *privat-docent* of Pathological Anatomy and Forensic Medicine, has been promoted to the rank of Extraordinary Professor.—*Tübingen :* The Chair of Midwifery and Gynæcology having been declined by Professor Fehling, of Halle, the faculty has made a fresh selection of names—(1) Dr. Bumm, of Basle; (2) Dr. Löhlein, of Giessen; and (3) Dr. Döderlein, of Groningen.—

Digitized by Google

Vienna: Dr. S. Fränkel has qualified as *privat-docent* of Medical Chemistry.—*Würzbury:* Professor Kölliker, on account of his advanced age, is giving up the teaching of Descriptive Anatomy and will confine himself to Microscopical Anatomy for the future. The chair of Descriptive Anatomy has been offered to one of his old assistants, Dr. Philipp Stoehr, at present professor in Zurich. Dr. Eduard Koll has qualified as *privat-docent* of Internal Medicine.—*Yale:* Dr. J. Slade Ely has been appointed Professor of Medicine.

PRESENTATIONS TO MEDICAL MEN.—The following gentlemen have received presents from the local ambulance classes as tokens of appreciation of their honorary instruction in first aid—namely, Mr. Alexander A. McNab, M.B. Glasg., from the members of the Workhouse division of the St. John Ambulance Association, Bradford, a gold pin set with diamonds; and Mr. Sydney Partridge, M.D. Edin., from the members of the Darlaston centre of the St. John Ambulance Association, a barometer.—Dr. Beattie on Saturday last, at a social gathering held at Shaw Cross, Dewsbury, in connexion with the St. John Ambulance Association, was the recipient of a dressing-case presented by the male and female members of the above association, in appreciation of his services as their lecturer.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.—Concerts in honour of the Diamond Jubilee were given at this hospital on July 10th, in the morning, afternoon, and evening, the arrangements being under the direction of Miss Janotha. The Duchess of York, attended by Lady Mary Lygon and the Honourable Derek Keppel, arrived at the hospital about half-past three, and were received by the Bishop of Marlborough, Colonel Porter, Sir William Gowers, Dr. Ferrier, Mr. Silva, and Mr. Burford Rawlings. The Duchess visited several of the wards and spent some time in the concert-room, making a stay of about an hour altogether. The general company included the Countess of Bantry, Lord and Lady Amherst of Hackney, Lady Russell Reynolds, Lady Crichton Browne, Sir Henry and Lady Burdett, Dr. Buzzard, General and Mrs. McMahon, Mr. R. J. Seddon (Premier of New Zealand) and Mrs. Seddon, the Rev. W. R. Greenhill (chaplain), and Miss Tweed (lady superintendent). At night the hospital grounds were brilliantly illuminated. Endeavours are at present being made to complete a Commemoration Fund of £10,000, a considerable portion of which has been already raised.

LITERARY INTELLIGENCE.—The prospectus has just been issued by the publishing firm of F. Enke, of Stuttgart, of a forthcoming "Handbook of Practical Medicine," edited by Dr. W. Ebstein and Dr. Schwalbe. The work is to be in five volumes and will appear in instalments. The first "lieferung" is to be issued at the beginning of 1898 and the last, it is hoped, about the middle of 1899. Among the long list of contributors may be noted the names of Professor Liebermeister and Professor Lenhartz, who write on the Respiratory Organs; Professor Laache, of Christiania (Diseases of the Blood); Professor Pel, of Amsterdam (Diseases of the Stomach); Professor Pibram, of Prague (Diseases of the Intestines); Professor Rosenstein, of Leyden (Diseases of the Kidneys); and Dr. Jolly, of Berlin (Neuroses); the aim being to secure writers who have specially studied the subjects assigned to them. It is instructive to find that nearly every section is supplemented by a surgical article, and it is further intended to introduce each section by remarks on the general clinical and therapeutical characters, especially the methods of examination. The price of the complete work is stated to be about 80 marks (£4).

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—News has just been received from Batavia of the sudden death of Dr. P. C. Plugge, he having gone to study in the great tropical botanic garden of Buitenzorg. He was born in Middelburg, Zeeland, in 1847, studying first at Amsterdam, where he received a gold medal for his thesis on Carbolic Acid as a Disinfectant. He was afterwards Assistant in the Physiological Laboratory in Groningen, and for a short time he took charge of the chemical laboratory in Tokio by special invitation of the Japanese Government, from which post, however, he was soon recalled to become Professor of Pharmacy and Toxicology in Groningen. His published papers are numerous and varied, comprising such subjects as the Chemical Effects of Light, the Poisonous Constituents of the Ericaceæ, Aconitine, Andromedotoxin, &c.—The deaths of the following eminent foreign medical men have also been announced:—Dr. W. Marmé, Professor of Pharmacology in Göttingen.—Dr. Fissore, Extraordinary Professor of Medical Pathology in the University of Turin.—Dr. Paulin Hulin, Medical Officer to the Hospices and Prisons, Louvain, Chevalier of the Legion of Honour, at the age of fifty-five years.—Dr. Emile Legros, Professor of Physiology in Brussels, and a well-known ophthalmic surgeon, suddenly, in his thirty-seventh year.—Dr. Debrou, formerly surgeon to the Orleans Hospital.—Dr. Don José de Letamendi, Professor of General Pathology in the Central University, Madrid.—Dr. Don José de Antelo, Professor of Surgical Pathology in the Manilla Medical School.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—The annual meeting of this association was held at the rooms of the Medical Society of London on Wednesday, July 7th, when the following officers were elected for the year 1897-98:—President: Dr. T. Outterson Wood (in the place of Professor W. C. Arnison). Vice-presidents: Dr. S. Fielden and Mr. T. H. Openshaw. Council: Dr. C. C. Cripps, Dr. C. J Cullingworth, Dr. J. W. Hembrough, Dr. F. S. Palmer, Dr. H. B. W. Paige, Dr. H. T. Herring, Dr. G. H. Philipson, Mr. G. W. Ridley, Dr. W. J. Sheppard, Dr. T. C. Squance, and Dr. R. Steele. Honorary treasurer: Dr. W. C. Beatley. Honorary secretaries: Dr. W. D. Arnison and Dr. R. H. Milson. After the meeting the members dined together at the Café Royal, Dr. T. Outterson Wood, President, being in the chair. The usual patriotic toasts having been proposed by the President, Mr. H. T. Butlin proposed "The University of Durham," and Professor Philipson responded. The President, in proposing "Success to the Durham University Medical Graduates' Association," gave an interesting account of the history of the Medical College from its foundation in 1832 to the present time, and congratulated the association upon its great success, numbering, as it does, nearly 300 members. The honorary secretaries replied. Sir James Crichton Browne, who was a former lecturer at the College, and who was elected an honorary member of the association, proposed the health of the President, and Dr. Cullingworth proposed the Visitors which was responded to by Dr. Ernest White. Among those also present were the President of the Royal College of Surgeons of England, Sir Wm. MacCormac; the Treasurer of the Royal College of Physicians of London, Sir Dyce Duckworth; the President of the Royal Medico-Chirurgical Society, Dr. Howship Dickinson; the President of the Medical Society, Mr. Reginald Harrison; the President of the Durham University Medical College, Professor Philipson; the President of the Harveian Society, Dr. R. H. Milson; the Coroner for the Central District of the county of London, Dr. Danford Thomas; and members and guests to the number of fifty-seven.

PRESENTATION TO PROFESSOR JOHN ATTFIELD, F.R.S.—Professor John Attfield was presented on Saturday last, at Watford, on his retiring from the chair of Practical Chemistry in the School of the Pharmaceutical Society of Great Britain, with a handsome testimonial, consisting of an autograph album and silver plate. The former contained the names of eminent men of science of England and the continent. On the silver tray the following inscription is engraved: "An Album of Autographs, this Silver Tray, and a Silver Tea and Coffee Service were presented to Professor John Attfield, F.R.S., by one thousand grateful pupils and many public friends in all parts of the world, on his retirement from the chair of Practical Chemistry held by him for thirty-four years in the School of Pharmacy of the Pharmaceutical Society of Great Britain."

MEDICAL MAGISTRATE.—Sir Robert M. Craven, F.R.C.S. Eng., of Hull, has been placed on the Commission of the Peace for the East Riding of Yorkshire.

THE committee of the Central London Ophthalmic Hospital, Gray's Inn-road, have received a donation of £400 from Mrs. James Packe towards the building fund of the hospital.

WE are glad to announce that Mr. W. R. M. Wynne, the Lord-Lieutenant of the county of Merionethshire, has appointed Dr. John E. Jones, J.P., of Bryn-y-Ffynon, Dolgelley, a Deputy-Lieutenant of the county.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Lunacy Bill.

THIS Bill has been read a second time in the House of Lords, and has at present every prospect of a quick passage through that Chamber.

Infant Life Protection Bill.

This measure, after passing the House of Lords, is now in the House of Commons, where it has been read a second time and referred for detailed consideration to the Grand Committee on Law.

Verminous Persons Bill.

This Bill to give local authorities power to offer to persons infested with vermin such means of cleansing and disinfecting as they possess was read a third time on Wednesday, July 7th, in the House of Commons. Local authorities are at present without this power, and verminous persons are treated at workhouses or casual wards and so rank as recipients of Poor-law relief.

Plumbers Registration Bill.

The Bill for establishing a national system of registration for plumbers failed to get through the report stage on Wednesday, July 7th, and in consequence has now little chance of being passed during the present session.

New Naval Hospitals.

In the Naval Works Bill now before the House of Commons the Admiralty take power to build two hospitals for the treatment of zymotic diseases, one at Haslar, Portsmouth, and the other at Haulbowline, Cork.

Workmen's Compensation Bill.

During the report stage of this Bill in the House of Commons several matters of special interest to medical men were discussed. For instance, various proposals were made for the periodical examination by duly qualified medical practitioners of workmen who are receiving compensation from their employers, and as the outcome of several debates there was inserted in one of the schedules of the Bill a provision that any workman claiming compensation under the Act shall, if so required by the employer from time to time, submit himself for examination by a duly qualified medical practitioner provided and paid for by the employer. The provision further says that if the workman refuses to submit himself to such examination or obstructs it, his right to the weekly payments shall be suspended until the examination takes place, and that if the workman objects to the examination he may appeal to the arbitrator whose decision in the matter shall be final.

HOUSE OF COMMONS.

TUESDAY, JULY 6TH.

Prison Rules as to Corporal Punishment.

Sir M. White Ridley said in reply to Mr. J. A. Pease that he was laying a new rule on the subject of corporal punishment in prisons on the table of the House. He could not deal with the matter so fully as he had wished without the further legislation which he had proposed to Parliament, but which there had been no time to pass during the present session.—Mr. Powell-Williams with regard to military prisons said that it was proposed to reduce the number of offences for which corporal punishment could be awarded and to require that the order for it be given by three instead of two visitors.

Kissing the Book.

Sir Walter Foster asked the Attorney-General whether he had considered the form in which the oath was administered in courts of justice in England with reference to the sanitary objections urged against it, and whether it was the intention of the Government to make any proposals for amending the law so as to abolish the objectionable practice known as "kissing the book."—The Attorney-General (Sir Richard Webster) said that he could only repeat his reply to the hon. member that he thought the sanitary objection to the present method of administering the oath had been somewhat exaggerated. Personally he believed that the option at present existing of swearing in the Scotch form, which was becoming every day more generally known, was sufficient. It was not the intention of the Government to amend the law, at any rate, during the present session. Dr. Farquharson asked whether the Attorney-General would take steps to make it more generally known that witnesses had a right to be sworn in the Scotch style.—The Attorney-General replied that he had made inquiries and had ascertained that in practically all the courts public notices had been issued and, as he had stated, the option was becoming more generally known.—Mr. Patrick O'Brien asked the learned gentleman to describe the Scotch form.—The Attorney-General said he must refer the hon. member to the Lord Advocate.

Fever Epidemic in Ireland.

Mr. Crilly asked the Chief Secretary to the Lord Lieutenant of Ireland if he had had any recent report from the officials of the Local Government Board of Ireland dealing with the outbreak of fever in the Belmullet Union; whether he was aware that on June 6th 44 persons were prostrated by fever in the South Island of Inniskea out of a total of 37 families; that 20 cases were reported last week; that two of the nurses attending these fever cases in Inniskea had been attacked by fever, and were on Friday last brought to the mainland and placed in hospital; and that three other nurses had been telegraphed for to Dublin and an advertisement published for a second medical officer; and what steps, if any, the Government proposed to take to deal with the existing distress, both from famine and fever, in the Belmullet Union.—Mr. Gerald Balfour said that he had received only the day previous a report from the medical inspector of the Local Government Board respecting the outbreak of fever on Inniskea Island. It had not been found possible in the brief interval since the question was placed on the paper to ascertain the number of fever patients on June 6th, but it appeared that on the following day there were 12 cases in the acute stage and 30 in the convalescent stage. One new case was reported last week, not 20 cases as alleged. There were now, in all, 14 cases in the acute stage of fever, 3 under observation, and 18 in the convalescent stage. Two of the nurses contracted the fever, and were under treatment in Belmullet. Additional nurses to replace them, as well as the resident medical officer, were landed on the island on Sunday. All the necessary steps had been taken by the Board of Guardians acting as the sanitary authority, and the Local Government Board would continue to advise and assist them in the administration of their statutory powers. He was not aware of the existence of famine in the Union.

The Case of Dr. Bynoe.

Mr. Bartley asked the Home Secretary whether he was aware that in the case of Dr. C. A. Bynoe, who was in 1892 convicted at the Old Bailey of forgery, a woman of the name of Rose Ripsher had confessed to the Home Office authorities that she alone was guilty of the forgery and that Dr. Bynoe was convicted in error, and whether he had taken steps to release Dr. Bynoe.—Sir M. White Ridley said he was fully aware of this woman's confession. The case of the prisoner Bynoe had been repeatedly under consideration, but neither his predecessors nor himself had found any reason to doubt the justice of his conviction.

THURSDAY, JULY 8TH.

Experiments on Living Animals.

Mr. John Ellis asked the Home Secretary whether the figures of experiments on living animals contained in Return No. 239 of this Session were obtained from the licencees who performed them, and in that case whether any steps were taken to verify their accuracy; whether each of the "licensed places" was inspected during the year to which the return related, and how many of them more than once; whether any of the visits of inspection were surprise visits, and, if so, how many; and, whether he had personally satisfied himself that the licences and certificates were all issued only to such places and persons, and with such objects, as were contemplated by the Cruelty to Animals Act, 1876.—Mr. Jesse Collings, for the Home Secretary, replied as follows:—Yes, the returns are obtained from the licencees, and the check of course upon them is supplied by the visits of the inspectors, which, with a few exceptions, are paid without notice. Four registered places at which no licences were in force, and the laboratory attached to the Board of Agriculture, which was only registered on Dec. 1st, were not visited during the year. Five places were visited once only, eight twice, twenty-five three times, two four times, three five times, and one six times. No licencee was found during any of these visits to be exceeding his powers. The answer to the last clause of the question is in the affirmative.

Qualifications of Dispensers.

Mr. Lyttelton asked the President of the Local Government Board if he could state why the standard of qualification for appointment as dispenser to a Poor-law union had been reduced so that persons other than those possessing a statutory qualification in pharmacy were now eligible for such appointments; and whether, having regard to the special technical training required in such dispensers, the Local Government Board would take steps to obtain for the sick poor in the various unions under their jurisdiction the security afforded by dispensers possessing a statutory qualification to dispense medicines.—Mr. Chaplin replied that in June, 1895, the Local Government Board issued an order by which compounders of medicines duly qualified in accordance with the regulations for the Army Medical Staff Corps were recognised as qualified for appointment as dispensers by boards of guardians. The Board had previously issued similar orders as regards particular cases. The order referred to was not issued without careful consideration.

Dog Muzzling.

Sir M. White Ridley said, in reply to a question by Mr. Schwann that he was able to quote the numbers given in the judicial statistics of persons proceeded against for offences generally in relation to dogs, a heading that included besides infringements of muzzling orders, infringements of certain statutory requirements as to keeping dogs, muzzled or otherwise, under proper control. The number of persons so proceeded against in the years 1893, 1894, and 1895 were 3539, 9265, and 31,434, of whom respectively 2952, 7803, and 27,527 were convicted. No doubt the great majority of the proceedings were for infringements of muzzling orders.

Plague Administration at Poona.

Mr. Weir asked the Secretary of State for India, having regard to the reply given by Lord Sandhurst as to certain allegations relative to the methods adopted at Poona for the suppression of the plague, and more particularly as to the statement that in the case of the inspection of the inmates of houses there was no possibility of indignity to native women, owing to the presence of lady doctors and other ladies with search parties, would he state the number of lady doctors at Poona and their names.—Lord George Hamilton said he was informed by the Bombay Government that the lady doctors engaged with search parties were Miss Bernard, M.D., Miss Crawley, L.R.C.P., Miss Dids, hospital assistant, and Mrs. Goodall, a Parsee with some medical qualifications. Other ladies were Mrs. Taylor, Miss Kelly, Mrs. Fernandez, Mrs. Balubai Awte (Hindu), Mrs. Bhimabai Awte (Hindu), Miss E. Barnard, Miss Tarkhad (Hindu), Miss M'Intosh, and the Hong Kong nurse, when not employed as a nurse.—Mr. Swift MacNeill also addressed a question to the Secretary of State on this subject.—Lord George Hamilton in the course of his reply read the following telegram from the Government of Bombay:—"Street inspection mentioned in Rand's letter of April 9th last arose thus: When searching was first instituted, women in many houses remained in dark rooms, where it was impossible to see whether they were ill, so householders were desired to cause their women to come into open place, such as reasonably light room or courtyard or street, merely that it might be seen whether they looked ill. If there appeared reason for actual medical examination, it was conducted with every regard for decency, not in public, and in case of women never by

Digitized by Google

anyone but a woman, unless no objection was raised to examination by a commissioned medical officer. Allegation that women were stripped in street to detect plague symptoms is malevolent fabrication. The native gentlemen and lady doctors must have been cognisant of street inspection, as of all that went on."

MONDAY, JULY 12TH.

London Water Question.

Mr. Causton asked the President of the Local Government Board whether his attention had been drawn to the fact that the Southwark and Vauxhall Water Company was only giving an intermittent supply of water to many of the large blocks of workmen's dwellings in certain parts of West Southwark, and was creating a grave danger to public health; and whether he proposed to take any, and if so what, measures to compel the company at once to comply with the law, and give a constant supply.—Mr. Chaplin replied that the Local Government Board had received no complaints of the water-supply being intermittent in the cases referred to, and he had, therefore, no compulsory powers even if the facts were as stated. When notice was given of the question, he instructed General Scott to make inquiries into the matter. The company did not admit the allegations, and he was informed to-day by the company that the buildings in West Southwark continued to be well supplied with water, and no complaint existed.

Mr. Tritton asked the President of the Local Government Board whether, in view of the great inconvenience and danger to which the inhabitants of Norwood had been lately exposed by the failure in the water-supply, he would represent very strongly to the Lambeth Waterworks Company the necessity of immediate notice being given to consumers in future should it be found necessary for any reason to restrict or discontinue the ordinary supply.—Mr Chaplin replied that he had communicated with the Lambeth Water Company and impressed upon them the great importance of giving early notice, so far as circumstances would permit, of any probable deficiency in the water-supply of their district. He thought he should add that the deficiency in the supply was very sudden, that it was occasioned by causes which could not have been foreseen, and was at an end after five or six days. Under such circumstances it would have been very difficult to give notice to the many thousands of water consumers in the district in time to be of practical service.

Bubonic Plague.

Mr. Knox asked the President of the Local Government Board whether his attention had been called to the bacteriological report and the despatch of March 10th from the Government of India showing that mice inoculated with an infusion from grain infected by the plague bacillus died in some cases, though the grain had been for thirteen days free from fresh infection, and that the bacilli might at a later date re-acquire toxic properties under favourable conditions; and whether he could state what steps had been taken to prevent the introduction of the plague into the United Kingdom.—Mr. Chaplin replied: My attention has been drawn to the report and despatch referred to. From the report it would appear that in an experiment in which mice were deliberately injected beneath the skin with preparations of nine different species of grain which had been purposely infected with microbes of bubonic plague, one single mouse injected with one of these nine preparations died after twenty-four hours, whilst all the others survived. As regards the mouse that died, it is stated that it "showed no appearances microscopically or otherwise of having succumbed to bubonic infection," and I am advised that no scientific conclusion should be drawn from such a result. I do not gather that the report shows "that the bacilli must at a later date re-acquire toxic properties under favourable conditions." What the report says is that the Government of India are advised that the experiments are not conclusive, since such re-acquirement of toxic properties may be possible. The steps which have been taken to prevent the introduction of plague into England and Wales are embodied in an Order relating to plague, cholera, and yellow fever, which was issued by the Local Government Board in November, 1896. These regulations were brought under the direct notice of every urban, rural, and port sanitary authority in England and Wales. I also instructed medical inspectors of the department to pay special visits to a number of ports which are in somewhat frequent communication with ports of India.

TUESDAY, JULY 13TH.

Experiments on Living Animals.

Mr. Weir asked the Home Secretary whether he had yet been able to institute the promised inquiry into the allegations made by Dr. E. Berdoe in regard to the use of curare in the practice of vivisection; and, if so, would he state the result of his inquiry.—Sir M. White Ridley replied that he had made full inquiry into the allegations contained in the letter and statement which the hon. Member forwarded to him, and found that they were absolutely baseless. The experiments referred to were performed on animals under full chloroform anæsthesia; the morphia, to which alone allusion was made in the published account of the experiments, being used in addition. Curare was used, but not as an anæsthetic.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ADAMS, JOSEPH DIXON, M.D. St. Andrews, M.R.C.S., L.S.A., has been appointed a District Medical Officer of the Langport Union.

ALEXANDER, J., L.R.C.S. Edin., has been re-appointed Joint Parochial Medical Officer and Public Vaccinator, Leslie.

BAILEY, T. RIDLEY, M.D. Edin., has been appointed Certifying Factory Surgeon for the Bilston District, vice James Wells, Wolverhampton, resigned.

BOWHAY, A., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Calstock District Council.

CLARK, J. S., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Mortonhampstead Sanitary District of the Newton Abbot Union, vice F. G. Engelbach resigned.

DALY, C. F., M.D. Irel., L.R.C.S. Edin., has been appointed Medical Officer for the Silverdale Sanitary District of the Wolstanton and Burslem Union.

EDWARD, A. A., M.D., C.M. Edin., has been appointed Medical Officer for the No. 1 Rawtenstall Sanitary District of the Haslingden Union.

EDWARDS, L. C., M.B., C.M. Edin., has been appointed Casualty Surgeon to the Bristol General Hospital.

FFRENCH, D. M., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Debenham Sanitary District of the Bosmere and Claydon Union.

HARRISON, JAMES, M.R.C.S., L.R.C.P. Edin., has been appointed Medical Officer to the East Grinstead Isolation Hospitals.

HAY, H. D., M.B., C.M. Edin., has been re-appointed Joint Parochial Medical Officer and Public Vaccinator, Leslie.

HILDYARD, ROBERT LOXHAM, M.R.C.S., L.S.A., has been re-appointed Medical Officer and Public Vaccinator of the 2A and 2B Districts of the Langport Union.

JELLY, G. AUBREY, L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon and Registrar at the Royal Eye Hospital, Southwark, London.

MORGAN, J. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Llandulas and Llanwrtyd Sanitary District of the Builth Union.

MUNDEN, CHARLES, M.R.C.S., L.S.A., has been re-appointed Medical Officer of the 3C District of the Langport Union.

O'CONNOR, J. E., M.B., B.Ch. Irel., has been appointed Medical Officer of Health by the Lowestoft Town Council.

PARKINSON, C. H. W., M.R.C.S., D.P.H. Edin., has been re-appointed Medical Officer of Health by the Wimborne Urban District Council.

PARTRIDGE, SYDNEY, M.D. Edin., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer by the Darlaston Urban District Council, vice Samuel Partridge, resigned.

SMITH, T. F. HUGH, F.R.C.S. Eng., has been appointed Medical Officer to the Bartholomew's Hospital Convalescent Home.

SQUIRE, M. F., M.B., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer for the Infirmary and Workhouse of the parish of Paddington.

TORRENS, J., M.D., M.S. Irel., has been appointed Medical Officer for the Quatt District School, and Medical and Vaccination Officer for the Calverley and Wirehl Sanitary Districts of the Bridgnorth Union.

WATSON, W. D., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Leigh-on-Sea Urban District Council.

WILKINS, WALTER, M.R.C.S., L.R.C.P. (late H.S. and H.P., Charing-cross Hospital), has been appointed House Surgeon to St. Peter's Hospital, Henrietta-street, W.C.

WILSON, JAS. S., M.D. Glasg., D.P.H. Camb., has been appointed the Certifying Surgeon for Walsall and Bloxwich Districts, vice J. Wood, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRADFORD UNION WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100 per annum, with prescribed rations, washing, and apartments in the Workhouse. Applications to the Clerk to the Guardians.

GENERAL HOSPITAL, Nottingham.—Assistant House Physician for six months. Board, lodging, and washing in the hospital, and an honorarium of £10 10s. will be given conditionally.

GRIMSBY AND DISTRICT HOSPITAL, Grimsby.—Resident House Surgeon. Salary £80 per annum, with board, lodging, and washing.

HARTISMERE UNION, Suffolk.—Resident Medical Officer and Public Vaccinator for the Gislingham District. Salary at the rate of £60 per annum, exclusive of vaccination fees and such other extra fees as are allowed by the Local Government Board. These average about £25 per annum. Applications to the Clerk, Guardians' Offices, Eye.

HEREFORD GENERAL INFIRMARY.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished rooms, board, washing, gas, coal, and attendance.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, London.—House Surgeon for six months, unmarried. Salary £20, with board and residence in the hospital.

HULME DISPENSARY, Dale-street, Stretford, Manchester.—House Surgeon. Salary £130 per annum, with apartments, attendance, coal and gas.

KENSINGTON UNION.—Second Assistant Resident Medical Officer for the Workhouse and Infirmary. Salary £80 per annum, with apartments, board, and washing, subject to the statutory deduction under the Poor-law Officers Superannuation Act, 1896.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Assistant Resident Medical Officer for six months. Residence, board, and washing provided, and an honorarium given on the termination of the appointment.

MACCLESFIELD GENERAL INFIRMARY.—Senior House Surgeon. Salary £100 for the first year, with board and residence. Also Junior House Surgeon. Salary £70 per annum, with board and residence at the institution.

MEMORIAL HOSPITAL, Jarrow-on-Tyne.—House Surgeon. Salary £80, rising £10 annually to £100. Board and residence provided in the hospital. Applications to Mr. J. Campbell, Surgeon, Ivy Bank, Jarrow-on-Tyne.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officer at the South-Western Fever Hospital, Landor-road, Stockwell, S.W.,

Digitized by Google

unmarried. Salary £160 the first year, £180 the second year, and £200 the third and subsequent years of service, with board, lodging, attendance, and washing, subject to statutory deduction under the Superannuation Act, 1896. Applications to the Clerk to the Board, Chief Office of the Board, Norfolk-street, Strand, W.C.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Assistant Surgeon. Also Surgeon.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer for six months. Salary £30 per annum, with board, attendance, and washing.

MILL-ROAD INFIRMARY, Liverpool.—Medical Superintendent. Salary £500, with unfurnished house, coal, gas, rates, and taxes, inclusive of all fees. Applications to the Clerk to the Guardians, West Derby Union, Brougham-terrace, Liverpool.

NORTH WALES ASYLUM, Denbigh.—Second Assistant Medical Officer. Salary £100, with board, washing, and apartments. No beer allowance, and no pension given. Applications to the Clerk to the Visitors, Denbigh.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London, N.W.—Assistant Resident Medical Officer for four months. Salary at the rate of £50 per annum, with board, residence, and washing.

RIPON DISPENSARY AND COTTAGE HOSPITAL.—Resident House Surgeon and Dispenser, unmarried. Salary £70 per annum, with board and lodging.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £30 per annum; board, lodging, and washing provided.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months. Board, lodging, and washing provided.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments, board, and washing.

ROYAL INFIRMARY, Aberdeen.—Medical Superintendent. Salary £350 per annum, without residence.

SHEFFIELD UNION.—Resident Assistant Medical Officer at the Union Workhouse, Fir Vale, Pitsmoor; single or widower. Salary £100 per annum, with apartments, rations, and the other usual allowances. Applications to the Clerk to the Guardians, Union Offices, Sheffield.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House Surgeon for two years. Salary £100 per annum, with board, lodging, and washing.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Fourth Assistant Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

ECCLES.—On July 11th, at 63, Sackville-road, Hove, Brighton, the wife of G. Tolcher Eccles, M.A., M.B. Cantab, of a son.

FERGUSON.—On July 9th, at Rutland-street, Edinburgh, the wife of James Haig Ferguson, M.D., F.R.C.P. Edin., of a son.

HAMER.—On July 8th, at Dartmouth-park-hill, N.W., the wife of W. H. Hamer, M.D., of a son.

LEWIS JONES.—On July 6th, at Kenilworth-road, Ealing, the wife of H. Lewis Jones, M.D., of a son.

OLIVER.—On July 10th, at 7, Ellison-place, Newcastle-upon-Tyne, the wife of Thomas Oliver, M.D., F.R.C.P., of a son.

RAMSAY.—On June 29th, at Jesmond Dene, Bournemouth, the wife of F. Winson Ramsay, M.S., F.R.C.S. Edin., of a son.

MARRIAGES.

BALDING—AUSTIN.—On July 7th, at St. Augustine's Church, Highbury New-park, Edmund Balding, L.D.S.R.C.S. Eng., eldest son of Edmund Balding, of Fairbridge House, Upper Holloway, to Violet Constance, third daughter of Edwin Austin, J.P., of Highbury New-park, N.

HALAHAN—GALTON.—On July 14th, at St. Paul's, Upper Norwood, by the Rev. H. Stevens, M.A., Vicar of Holy Trinity, Sydenham, assisted by the Rev. R. B. Ransford, M.A., Vicar of St. Paul's, S. Crosby Halahan, of Leigh Manor, Cuckfield, Sussex, eldest son of the late Colonel S. H. Halahan, of Haighlands, Sydenham-hill, to Maud Ethel, second daughter of John Galton, M.D. Lond., of Chunam, Sylvan-road, Upper Norwood.

LAUCHLAN—HILL.—On July 7th, at the Congregational Church, Grafton-square, Clapham, Charles A. Lauchlan, M.D., of Clapham-road, to Margaret Craven, seventh daughter of the late Rev. William Hill, of Beeralston, Devon.

MARTINE—TAYLOR.—On July 13th, at St. Michael's Church, Edinburgh, William Robert Martine, M.B., C.M. Edin., second son of the late William Martine, M.D., Haddington, to Dora, third daughter of the late Charles S. Taylor, S.S.C., Edinburgh.

MATTHEWS—DODD.—On July 7th, at All Saint's, Norfolk-square, W., Samuel Ryder Russell Matthews, M.R.C.S., L.R.C.P., son of the Rev. Andrew Matthews, Rector of Gumley, Leicestershire, to Katharine Frances, youngest daughter of John T. Dodd, of Cambridge-terrace, Hyde-park.

DEATHS.

COLLINS.—On July 13th, at Sydenham, the residence of his son, Dr. Thomas Collins, formerly of 28, Harcourt-street, Dublin, in his 89th year. Funeral at Norwood Cemetery on Thursday, July 15th, at 2.30.

ROGERS.—On July 12th, at 404, Commercial-road, E., George Arthur Rogers, M.R.C.S., L.S.A., Medical Officer of Health to the Limehouse District Board of Works, aged 54 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (21st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (22nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (24th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

TUESDAY (20th).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.).—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

THURSDAY (22nd).—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square).—5.30 P.M. Dr. T. D. Savill: Tuberculosis of the Skin.

FRIDAY (23rd).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.)—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

During the week marked copies of the following newspapers have been received:—*Derby Express, Bradford Observer, Peterborough Advertiser, North Wales Chronicle, Cardiff Times, Brighton Gazette, Scotsman, Western Mail, Herald of Wales, Times of India, Pioneer Mail, Brisbane Telegraph, Builder, Citizen, Ceylon Observer, Cape Times, Architect, Birmingham Gazette, Newcastle Leader, Manchester Guardian, Market Harborough Mail, Bedfordshire Times, Leek Times, Liverpool Daily Post, Leamington News, Tyrone Constitution, Wellingborough News, Leeds Mercury, Melbourne Age, Llandudno Directory, Norwich Mercury, Wolverhampton Chronicle, Dundee Courier, Sussex Daily News, Burnley Express, Hampshire Chronicle, Berkhamsted Times, Bristol Mercury, Andover Advertiser, Midland Times, Coleshill Chronicle, Shrewsbury Chronicle, Yorkshire Post, Rushden Echo, Sanitary Record, Rangoon Times, Surrey Advertiser, Hertfordshire Mercury, Local Government Chronicle, Reading Mercury, Newbury Weekly News, Glasgow Herald, Sunday Times, Local Government Journal, Weekly Free Press and Aberdeen Herald, Morning Herald, South Wales Daily News, Central Somerset Gazette, Galignani Messenger, Kidderminster Times, Cardigan Observer, Hastings Observer, Exmouth Chronicle, Falkirk Herald, Dewsbury District News, Blackpool Times, West Middlesex Herald, &c., &c.*

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TESTIMONIAL TO MR. W. J. C. MILLER.

WE mentioned in our issue of July 3rd, that some of his friends, contributors to the mathematical columns of the *Educational Times* and others, were forming a fund to present a testimonial to Mr. W. J. C. Miller, the lately retired Registrar of the General Medical Council. Included in the list of subscribers submitted to us are the names of the following members of the medical profession:—

	£	s.	d.		£	s.	d.
Sir H. W. Acland... ...	1	1	0	Dr. G. G. Morrice	0	5	0
Mr. D. Biddle	1	1	0	Sir James Paget	1	1	0
Dr. H. Gervis	1	1	0	Sir John Simon	1	1	0
Rev. Dr. Haughton ...	1	1	0	Professor Struthers... ...	1	1	0
Lord Lister	1	1	0	Mr. Thomas Wakley, Jun.	1	1	0
Dr. Donald MacAlister	1	1	0				

We understand that although the movement originated with mathematical friends of Mr. Miller, the Honorary Treasurer (the Rev. Robert Harley, M.A., F.R.S., Rosslyn, Westbourne-road, Forest-hill, S.E.) will be glad to receive any subscriptions which medical friends may wish to send.

Juniper.—The arrangement does not commend itself to us, but it would appear not to be illegal and not to traverse any regulations of the corporation to which our correspondent belongs.

DISTRICT NURSING ON A PROVIDENT BASIS.

DR. JAMIESON B. HURRY, Abbotsbrook, Reading, will be glad to hear of any centre where district nursing has been organised on a provident basis, or where a payment is required, in return for the services of the district nurse, from all persons except those actually destitute. A copy of the annual report of any such centre will be welcome.

THERAPEUTIC TATTOOING IN EGYPT.

IN May last Professor Lannelongue communicated to the Académie des Sciences in Paris a note by Dr. Fouquet, of Cairo, on tattooing as a means of treating disease. According to the author, the practice, which dates from the remotest times, is common in Egypt at the present day, and women still perambulate the streets in the native quarters of the city loudly proclaiming their readiness to perform, not only tattooing, but also ear-piercing and clitoridectomy. In support of the antiquity of the custom Dr. Fouquet gives a description of a mummy which he examined in 1892. It would seem that the remains are those of a priestess of Hathor named Ament, who lived at Thebes during the eleventh dynasty, some four or five thousand years ago. The body is that of a woman "still young but extremely emaciated, with her mouth open and twisted from anguish"; and the observer was led by these signs to the conclusion that death resulted from "generalised peritonitis." Commenting on the article in Duplay's *Archives* for July, M. Henri Meige justly takes exception to this retrospective diagnosis. If all the mummies presenting leanness and wry mouths are to be taken as having come by their deaths from peritonitis, then assuredly that malady must have been more deadly than the ten plagues, the condition described being universally found. As for the expression of anguish, the inference deduced is scarcely more justifiable, since mummified corpses are nearly always disfigured in the manner indicated. In the crypt of the church of Saint Michael at Bordeaux, for instance, there are a number of bodies which, owing to some preservative quality in the soil, have escaped decay, but only at the expense of contortions, more or less fantastic, that serve to convey the impression that the deceased had succumbed to painful affections. So much so, indeed, is this the case that quaint names have been bestowed by the local wits on the various groups constituting these lugubrious relics. Here, they say, we have an entire family who were poisoned by eating mushrooms; while that tall mummy, with his abdomen in shreds, was a porter who ruptured himself in the endeavour to carry too heavy burdens. The fact, nevertheless, remains, and abounds with interest, that the priestess Ament had marks of tattooing as well as traces of scarification on the lower part of her abdomen, although it does not seem at all probable that these operations were undertaken for the cure of an acute disease like peritonitis. They may have been performed with a view to prophylaxis, but it is more likely that preservation from witchcraft was the motive, if not simple adornment. Amongst the aboriginal tribes of Africa tattooing is still resorted to as a preventive of disease and accident, being regarded as a species of amulet or charm.

Mr. Mortimer Gray.—The treatment in question is a vulgar fraud.

WANTED A WORD OF ADVICE.

To the Editors of THE LANCET.

SIRS,—Would any medical *confrère* versed in such matters kindly give his advice through THE LANCET as to what annual fees, and what special conditions the medical officer of a society should stipulate for, if he were required to extend his functions as medical officer to the families of members. I am, Sirs, yours faithfully,

July 14th, 1897. D. J.

Triple Qual.—All information will be given to our correspondent by Dr. Major Greenwood, 243, Hackney-road, N.E.

EFFECTS OF WORKING IN COAL BUNKERS.

THE attention of Russian naval surgeons has for some time past been especially directed to the diseases observed amongst stokers and others employed in the engine-rooms, stokeholds, and coal bunkers of ships. Dr. Drezhnevich has recently published a paper on the effects of coal on the constitution of the atmosphere upon which he has been engaged for eight or nine years, having commenced it in 1888 in the chemical laboratory of the Cronstadt Naval Hospital under Dr. Shidlovski. The final part of the research was carried out in the Institute of Experimental Medicine attached to the St. Petersburg Medico-Chirurgical School under the direction of Professor Nenski. It was found that when rooms or bunkers containing a large quantity of coal were closed to the outer air the oxygen in them was greatly diminished, even at ordinary temperatures—that is to say, below 29° C., sometimes, indeed, disappearing altogether; at the same time, a very appreciable quantity of carbonic acid was found, which sometimes amounted to as much as 6 per cent.; hydrocarbons were also present, especially marsh gas, which generally existed to the extent of about 3 per cent. With higher temperature the vitiation of the contained air proceeded more rapidly, but carbonic oxide was not found, at all events, below 40° C. The special diseases noted among the men employed in the coal bunkers consisted of chronic anæmia and acute attacks of a spasmodic nature affecting parts or the whole body, indicating an insufficient supply of oxygen.

BORIC ACID IN MILK.

AT Barry Police-court on July 2nd three milkmen were prosecuted under Section 6 of the Food and Drugs Act. It appeared that each of the defendants had been asked to supply fresh milk, but instead had given milk with 0·3 per cent. of boric acid. The medical officer of health of Glamorganshire stated that this percentage was too high and would be injurious to a child, and he was of opinion that 0·1 per cent. of boric acid was quite sufficient to preserve the milk. The bench imposed a fine in each case of 40s. and costs, including advocation fee, amounting to £5 5s.

Nemo.—We cannot go so far as to insist upon a strict "boycott"; for, after all, the medical man's duties are primarily towards the public, and a strict "boycott" might lead to injustice to the suffering. Also, there are clubs and clubs. But if the clubs to which our correspondent refers are those where no wage limit is enforced, and where touts are employed to seduce the patients of other medical men to transfer their patronage to the club officer, we feel very strongly that no medical man should hold a post in such institutions. To do so is to break faith with the profession, while it is also to injure the suffering public by supporting a system that leads to indifferent medical treatment—the sort of treatment that must be the return for a starvation wage. The medical profession of the neighbourhood should look upon the matter in this light and then decide upon a common course of action.

ANGELICA AND SHEEP'S PARSLEY.

To the Editors of THE LANCET.

SIRS,—May I be allowed to say a few words with reference to the two cases of dermatitis caused by angelica, as recorded by Dr. David Walsh in THE LANCET of July 3rd? To my thinking the pallid young pastry-cook and his untutored friend must have actually gathered "cow parsley" (Æthusa cynapium) instead of the celestial herb they wanted for making a sweetmeat. Only a practised botanist would distinguish the genuine plant by its not possessing three long narrow pointed leaves at the base of each partial umbel. At the same time, its mischievous imitator is well known to blister the hands and to irritate the skin of those who cull it. If Dr. Walsh will kindly read what is told about "fool's parsley" in "Herbal Simples" he will readily appreciate my proffered suggestion. And in this the animal with the crumpled horn and the fool are identical, just as in the nursery rhyme where "the cow jumped over the moon." But, indeed, such a mistake, if followed up, has a serious bearing, and shows that some authoritative supervision ought to be exercised over heedless young simplers who roam the suburban fields in search of esculent wildings, else the halfpence of our children and the silver groats of our housewives may purchase for their intended delectation what will poisonously prove the "pernicious pasticcios, and the complex combinations of the confectioner." Thanking Dr. Walsh for his courteous quotation from my pages,

I remain, Sirs, obediently and faithfully yours,

July 10th, 1897. W. T. FERNIE.

R. S.—We never recommend practitioners, nor do we suggest treatment. Our correspondent's usual medical man can tell him whether a second professional opinion is necessary and can advise as to who should be invited to express it.

MEDICAL WOMEN.

WE are indebted to the *Gazette de Gynécologie* for the following items of intelligence, some of which have, however, already appeared in our columns. The Medical Commission of Louisiana has delivered a diploma, authorising her to engage in medical practice, to Miss Emma Wakefield, who belongs to the coloured race. This lady is said to be the first of her lineage who has received this distinction in the Southern States, and probably throughout the entire Union. She is the daughter of ex-Senator Wakefield, and was educated in the medical section of the Coloured University in New Orleans. The University of Vienna lately, for the first time, promoted a lady to the dignity of Doctor of Medicine. The new graduate, Mlle. Possanner d'Ehrenthal, had great difficulty in persuading the authorities to recognise her Zürich credentials, but was eventually permitted to present herself for examination before the Viennese board, and having triumphantly surmounted all the tests was duly admitted as a fully qualified practitioner. Following the example set by Vienna, the University of Budapest has, likewise for the first time, bestowed its medical degree upon a member of the female sex, the learned recipient being Mme. Wilhelmine Wartha, *née* Countess Hugonnay, whose husband is a professor at the Budapest Faculty of Medicine. The Medical College for Women in New York was destroyed by fire on April 22nd last. It was the sole recognised institution of its kind in America and contained upwards of 100 students, having been founded in 1864 by the sisters Elizabeth and Emily Blackwell. The building so unfortunately consumed was erected by private subscription at a cost of £25,000.

MR. JUSTICE LAWRANCE ON THE MEDICAL PROFESSION.

ON July 9th, at the Bristol Summer Assizes, during the hearing of a case in which a midwife was acquitted on a charge of murder, one of the witnesses stated that her daughter went to several medical men and told them of the serious state of the deceased, but they refused to come. She also saw a police officer and asked him if a medical man could not be compelled to attend. During his summing-up Mr. Justice Lawrance observed that he did not understand what the witness meant when she said that the medical men refused to come. From what he knew of the medical profession he did not think any member of it would refuse to attend a woman in so serious a condition. Probably the deceased, being a pauper patient, was under the care of the parish surgeon, who went on the receipt of a note from the relieving officer.

P. D. (Hoxton).—We do not agree that the paper in question failed in clearness. To us the points mentioned by our correspondent were sufficiently evident.

THE INTER-MARRIAGE OF DEAF-MUTES.

To the Editors of THE LANCET.

SIRS,—Both my parents had the misfortune to be deaf and dumb, my mother from birth and my father as the result of fever when six years of age. They had six children, including myself, two of whom died in infancy, the remainder being healthy and strong in every respect. The question which has been very unpleasantly brought before me recently is, whether in the event of my marrying the possibilities are that any children my wife might have by me would be similarly afflicted. I may say that there is no knowledge of any other member of my family previously ever having been so afflicted. I should be glad if you could give me an opinion, as, of course, the matter to me is a very serious one. Thanking you in anticipation,

I am, Sirs, yours faithfully,

July 9th, 1897. DEEPLY INTERESTED.

*** If the son of a deaf-mute marries, being himself of sound constitution and brain power, he is not likely to transmit mutism to his children. Mutism from early acquired deafness is not transmitted.—ED. L.

THE HEAT IN AMERICA.

WE have not in this country had any unusual heat up to the present time; the summer has hitherto been somewhat changeable—relatively cold alternating with hot days; but in America the heat seems to have been excessive, and as a consequence the amount of sunstroke and heat exhaustion unusually large. Between 300 and 400 deaths from sunstroke and heat apoplexy have been reported, and the amount of prostration, sickness, and physical discomfort attributable to the effects of the heat is incalculable. We hear, too, of the more or less wholesale exodus of the urban populations for watering-places, and of the efforts made by those left behind in the big cities to sleep outside their houses or on the top of them. It is quite possible that the heat-wave which is said to have prevailed in America may yet appear in this country, although, judging from the past, it is scarcely likely that the temperature here will reach the same height or be so persistent as it frequently is in America. The great thing, no doubt, to be done by those who are not compelled to remain in cities and towns is to get away from them to the seaside, the country, or the mountains, or to Switzerland. For those who cannot do so strict temperance in living, light and easy clothing composed of a texture freely permeable by the air, the occupation of freely ventilated rooms, especially bedrooms and dormitories, and the use of ice and iced drinks, with the avoidance of alcoholic stimulants, are the main points to be attended to, and the experience and common-sense of most people commonly cause them to have recourse to them.

Dubious.—The "remedy" in question is a quack preparation and is run on most mischievous lines.

"THE SAYINGS OF OUR LORD."

THE Egypt Exploration Fund, in the persons of Mr. Bernard P. Grenfell and Mr. Arthur S. Hunt, have recently discovered, as is now well known to everyone, a remarkable papyrus, the date of which is about 200 A.D., and the contents of which are reported sayings of Our Lord. The complete result of the excavations will be published in the next Archæological Report of the Fund, but in the meantime a fragment has seemed of such a remarkable character that a translation of it has been issued immediately. One saying, which has a familiar ring, merits quotation to a medical audience:—"Jesus saith, A prophet is not acceptable in his own country, neither doth a physician work cures upon them that know him." Here we have a remarkable addition to the well-known text from St. Luke (Chap. IV., v. 24): "No prophet is accepted in his own country," and an addition the practical shrewdness and accuracy of which every medical man will recognise. Who has not found special difficulty in treating his personal friends?

An Address

ON THE

PATHOLOGY OF PULMONARY PHTHISIS: A RETROSPECT.

Delivered before the Torquay Medical Society,

BY I. BURNEY YEO, M.D., F.R.C.P. LOND.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN KING'S COLLEGE, LONDON.

GENTLEMEN,—In casting about for a subject which might fitly occupy your attention at this your annual meeting, and form the main topic of the address which you have done me the honour to invite me to deliver, it occurred to me that a brief retrospect over a very remarkable chapter in the history of medical pathology might not prove uninteresting or uninstructive. I do not propose to ask you to follow me into a very remote retrospect; this backward survey will be limited to a period extending over very little more than a quarter of a century. But a few words of historical introduction may, however, be advisable in order to give something of coherence and completeness to the account I wish to present to you.

The subject I am thinking of is the Pathology of Pulmonary Phthisis. In the spring of the year 1873 a protracted discussion took place at the Pathological Society of London on the "Anatomical Relations of Pulmonary Phthisis to Tubercle of the Lung," and whoever will take the trouble—and it is certainly not an easy task—to read through the reports of this discussion can hardly fail to be struck with the extraordinary confusion of opinion and ideas therein presented. The period at which this discussion took place was an interesting one in the history of modern pathology, because I think it may be regarded as a critical period in the reputation and influence of the study of morbid histology as a pathological guide. At that time the whole field of pathology seemed, in the minds of many of the best reputed observers, to be identical with that of morbid anatomy and histology, with which it was then in imminent danger of being confounded, whereas it need hardly be said a true philosophical pathology takes in a far wider range. At that time the many earnest workers in the domain of morbid histology received perhaps rather more than an adequate meed of praise. Indeed, it was only by work of this kind that the young pathologist could hope to obtain any credit, and it followed as a consequence that the anatomical analysis of morbid products and the inferences drawn from them were pushed to an extreme, the evil results and the confusion attending which are well exemplified in the discussion to which I am now calling your attention. You must not suppose that it is merely an opinion of my own—that a sad confusion of ideas had been produced by an ill-considered and a too entire reliance on the results of histological analysis. It was recognised by the introducer of the discussion, Dr. Wilson Fox, and by others. "I would ask," Dr. Wilson Fox says at the end of the discussion, "is any chaos greater than the present?" and he adds: "I have often pitied the 'intelligent student' to whom we have appealed as our test of the definitiveness of our views." And, again, he asks, "Is there no way out of this confusion?" An eminent pathologist expressed his belief that "the use of the term tubercle tended to cause" this confusion, and proposed to discontinue its use. Another speaker of much authority also wished to throw overboard the word "tubercle." "At present," he says, "we are confused, hedged in, or hampered in a manner which is altogether ludicrous. Nobody knows what another means when he makes use of the word 'tubercle.' We cannot explain our views on the subject without entering into tedious statements concerning conflicting views." But as time has shown, the fault was not in the word "tubercle," but in this too exclusive method of investigation, in the then prevailing belief that nothing could be known of pathology outside the field of morbid anatomy and morbid histology. I was myself strongly convinced at the time of the dangers associated with this tendency, and I ventured to point out in that discussion "that the differences of opinion that existed amongst observers were greatly due to the circumstance that they had been looking too exclusively at one side of a many-sided subject," and "that they would be more likely to comprehend the true import of the anatomical evidences, the last words, as it were, of a disease when they regarded them in the light of the various circumstances that had attended its whole life-history."

But before we pursue this subject further let us take a very brief survey of the history of the prevailing opinions as to the pathology of phthisis during the first half of the present century. We will not go further back than the first publication of Laennec's views in 1811. In him we find the great originator of the idea of the unity of phthisis. All phthisis he regarded as "tubercular." He looked upon "tubercle" as an "accidental product"—foreign to the normal state and having no analogue in the healthy body—and the many modifications found in the lungs and other organs in the case of tuberculosis as caused by the evolutions of a unique heterogeneous substance, "tubercular matter." Laennec, with the insight of genius, saw identity of nature amidst apparent diversity of form and aspect, and he taught that isolated tubercle, miliary tubercle, grey granulations, and tuberculous infiltrations, grey and yellow, were all of the same pathological nature and origin. "The synthesis which he constructed of the different tuberculous processes has triumphed over all the attacks which it had to undergo, and has only now found its definitive confirmation in the most brilliant conquests of *modern technique*."[1] Laennec also maintained that tubercle was not only a substance foreign to the organism, but that it led a *special* life; the idea of its *specific* nature was distinctly in the mind of this great observer. These opinions of Laennec were violently attacked by Broussais (1826), whose views met with considerable favour in this country. Broussais maintained, in opposition to Laennec, that tubercle was purely and simply the result of inflammation, and that organs "irritated" to a certain degree and for a period more or less long ended by becoming tuberculous when they were so disposed. Tubercle, he said, was caused by chronic inflammation of the air passages, and was not therefore in any sense "specific." Broussais also, like a certain more recent observer, incriminated the pulmonary lymphatics in the tuberculising process. Tuberculisation, he affirmed, was attended by an inflammation of the lymphatic capillaries. The two essential points in the doctrine of Broussais as to the nature of pulmonary tuberculosis—viz., irritation as the cause and a lymphatic product as the effect—have held up to quite recent times a prominent place in the history of the pathology of phthisis. Louis shared the views of Laennec, but Andral, Cruveilhier, and Bouillaud (1837), and many others held with Broussais that tubercle was a result of inflammation and therefore non-specific. In 1844 Lebert attempted to demonstrate a specific histological structure in tubercle, but in this he signally failed, and his observations and conclusions were soon shown to be erroneous. In 1850 Laennec's doctrine was vigorously attacked by Reinhardt, and later by Virchow, the great authority attaching to whose name no doubt shook unduly the confidence which up to that time many had felt in the teaching of Laennec. Reinhardt declared that most of the anatomical appearances recognised as tuberculous were essentially inspissated pus, together with epithelial cells, filling the pulmonary alveoli, and were the results of catarrhal pneumonia. Virchow limited the application of the word "tubercle" to the grey granulation, and all the other forms of tuberculisation met with in phthisical lungs he declared to be the inspissated products of inflammation; he taught that pulmonary phthisis might be due either to the evolution of tubercle or to caseous hepatisation; and that phthisis, properly so called, was rather the result of caseous hepatisation than of tubercle. He reserved the name "tuberculous" to acute miliary tuberculosis. The idea of the unity of phthisis as in all cases a tuberculous disease was declared by him to be erroneous and the greater part of pulmonary phthisis to be due to inflammation. Thus we see that for Laennec and his followers there was but one kind of phthisis—i.e., tuberculous; and for Virchow and his followers there were at least two, one a caseous pneumonia and the other a rarer form—i.e., the tuberculous.

It was at this time that Niemeyer's teaching became prominent, and he maintained that phthisis depended on the caseous degeneration of the products of simple inflammation; that when in a phthisical lung the grey granulations

[1] Herard et Cornil, "La Phtisie Pulmonaire."

Digitized by Google

and pneumonia co-existed the granulations were secondary and consecutive; and so arose his famous dictum that "the greatest danger to which a phthisical patient could be exposed was that he should become tubercular"; and so it happened that in this country, as in Germany, Laennec's doctrine was discredited and the belief in the duality of phthisis or in "varieties" of phthisis became very general, and modifications of the inflammatory process were considered to be the chief agents in its causation.

In France, however, the most distinguished pathologists rallied to the standard of Laennec and maintained the unity of phthisis as a tuberculous disease; this was greatly due to the labours of Grancher, who, by studying and comparing the tuberculous granulation with a fragment of caseous pneumonia, without any apparent granulation, was able to formulate the law that "a nodule of caseous pneumonia has the same structure as the typical tuberculous granulation." This opinion soon secured the support of Rindfleisch in Germany and of Wilson Fox in this country, and somewhat later it had the vigorous support of Charcot, who was then professor of pathological anatomy in the Paris Faculty.

We thus reach the period of the discussion in the Pathological Society of London in 1873. But it seems desirable before referring to this event to go back a few years to 1866, to the period when Villemin claimed to have discovered the inoculability of tubercle; for this may be regarded as the initial step in connexion with a vast amount of careful investigation, which led ultimately to the discovery, published some sixteen years later, of the true nature of tubercle and the true pathology of pulmonary phthisis. The sensational character of Koch's discovery and the world-wide fame that justly followed it threw somewhat into the background the merit of the distinguished Frenchman whose investigations into the inoculability of tubercle started the labours of pathologists in the right direction towards the discovery of the truth. Speaking of Villemin's work Cohnheim says: "It was at this epoch (1860–1870) that a discovery was made in France, whence will date, if I am not mistaken, in the history of tuberculosis, not only an incomparable progress, but also a complete transformation in our manner of regarding this disease. Few discoveries, indeed, were capable of stirring medical opinion to so great a degree as the demonstration by Villemin of the transmissibility of tuberculosis." Villemin's observations form so important a step in the modern advance towards a true pathology of phthisis that it may not be uninteresting to give here his own account of his method of procedure, more especially as it was soon after to be imitated in this country with the remarkable result of negativing the true conclusions of Villemin, and so leading to a retrograde movement and to a retardation of the acceptance of the true pathology of phthisis. For Villemin's conclusions were correct, whereas the conclusions of his critics and imitators in this country were erroneous. Villemin, in describing his own procedure, says: "If we make in the ear of a rabbit, or in the groin or axilla of a dog, on a very narrow surface previously shaved, a subcutaneous wound, so small and shallow that not the smallest drop of blood shall appear, and if we insinuate securely and carefully a portion of tuberculous matter the size of a pin's head taken from a cow or a rabbit, already rendered tuberculous; or if, on the other hand, with a hypodermic syringe we instil under the skin of an animal a few drops of phthisical sputum, made more fluid by the addition of a little water, this is what we observe. The day after the operation the most careful palpation finds no trace of the matter inoculated—the margins of the wound are united—then, after at most four or five days, a slight swelling is observed, accompanied sometimes by heat and redness—and we can watch the progressive development of a local tubercle, varying in size from that of a hemp-seed to that of a filbert. For some time after the inoculation the animals present no appreciable alteration in their health. It is only at the end of from fifteen to thirty days that they are seen to be losing flesh. Some recover from this and put on flesh; others go on getting progressively weaker and fall into a state of marasmus, are often attacked with colliquative diarrhœa, and perish in a state of extreme emaciation. On post-mortem examination we find that the tubercles at the seat of inoculation are formed of a caseous mass around which are very often seen small yellowish granulations infiltrated for some distance in the inter-muscular connective tissue. The lymphatic glands communicating with the seat of inoculation are frequently swollen, present scattered granulations or tuberculous nodules, and sometimes end in complete caseous transformation. We generally find tubercles in the lungs, but the eruption of tubercles is not limited to those organs. It appears more or less abundantly in the lymphatic glands, the intestine, the liver, the spleen, the kidneys, &c. These organs are often stuffed with tubercles. The serous membranes, and notably the omentum and the mesentery, are sometimes riddled with innumerable granulations. According to the lapse of time since the inoculation and the greater or less rapidity with which the eruption occurs, we find the tubercles either grey and transparent, or yellow, caseous, and softened, or ulcerated and excavated. If the animals are killed before the fifteenth day it is rare to find tubercles in the organs. There elapses between the time of inoculation and that of the tuberculous eruption a certain time, which has appeared to us to vary from about ten to twenty days." Surely this is a striking picture of an infective parasitic process. It was found that caseous matter had the same infective property as the grey granulations. An important and influential academic commission confirmed the results announced by Villemin. Objections to his conclusions, however, arose in various quarters, and in this country Wilson Fox and Burdon Sanderson sacrificed a great number of rodents with the object of testing the correctness of Villemin's observations and inductions, and the results they arrived at had the effect, they maintained, of negativing his views. They stated that the results he had obtained were not peculiar to tubercle, but might be produced by almost any substance—pus, fragments of bone, bits of cork, of india-rubber, &c.—but it has now long been admitted that these observations and experiments of Fox and Sanderson, which produced so great an effect on professional opinion in this country at the time, and which were thought by many to be fatal to Villemin's conclusions, were themselves valueless on account of the absence of those antiseptic precautions which have since been shown to be needful in the conduct of such experiments.

Surely this is a remarkable lesson in the history of pathology! An extremely competent and careful observer, after a carefully planned, well-ordered, and minutely methodical series of observations, announces results and conclusions which prove to be absolutely true and accurate. Shortly afterwards other competent and careful observers make a long series of professedly similar observations and publish results which, it is maintained, negative the conclusions of their predecessor. As a consequence the progress of truth is retarded and error confirmed in men's minds. Villemin, however, found an able defender in Chauveau, whose skilful experiments and observations on the transmissibility of tubercle in oxen and horses afforded ample corroboration of the conclusions of Villemin. While these facts were fresh in men's minds the discussion at the Pathological Society of London was instituted in 1873, and it will surely be of some interest to examine briefly some of the opinions expressed by the eminent men who took part in that debate.

Although it was nearly ten years later that the parasitic and infective nature of tubercle became incontrovertibly proved through the discovery by Koch of the bacillus of tubercle, the idea that tubercle was of this nature was prominent in many minds at the time of this discussion, and it is not a little remarkable that this idea should be almost ignored by those who took part in this debate. Indeed, it is clear that the accuracy and conclusiveness of Wilson Fox and Sanderson's observations and experiments on the rodents are assumed by the debaters generally, and Villemin's labours and results are scarcely alluded to. In his two long speeches at the beginning and close of the discussion the introducer never once mentions the name of Villemin. It is exceedingly interesting in connexion with this chapter of pathology to find the opener of this debate, evidently after much tribulation of mind and sorely against his preconceived views, forced to the conclusion from the results of his own elaborate and very careful observations that phthisis is, in all its forms, one and the same disease—i.e., a tuberculous one; so that, although with some hesitancy and here and there a little lack of clearness, the outcome of his researches was to re-establish the doctrine of Laennec of the unity of phthisis. "Fifteen years ago," he says, "I came from Germany strongly impressed with the opinion that phthisis might be sub-divided into many absolutely diverse diseases—diseases diverse in their essential nature as well as in their apparent origin. I had a great many terms at the end of my tongue—broncho-pneumonia, caseous pneumonia, and scrofulous pneumonia,—but when I myself became a teacher I felt great

Digitized by Google

doubt and difficulty in saying what was not tubercle, and still more in saying what was tubercle. I came at last to the conclusion not to speak as I did in my earlier days, describing a lung as containing no tubercle because it did not contain what I imagined to be the only type of tubercle." And elsewhere he says: "It was my anxious wish to do something in my day and generation towards finding out a great many varieties of phthisis." It is needless, now that we know the true criterion of tubercle, to follow this most careful and conscientious observer through the laborious and minute anatomical and histological investigation which led him, in common with Rindfleisch, Charcot, Grancher, Cornil, and others, to the conviction of the unity of origin of the morbid processes which constitute phthisis; but these views as to the unity of phthisis were not acceptable to the majority of the authorities who took part in this debate. In a very lengthy and elaborate speech a well-known pathologist dogmatically asserted that phthisis was an affection "of which tubercle could no longer be considered as the pathological essence. ..... Laennec's central idea had been shown to be erroneous. ..... Phthisis had now been fully shown to be a non-tuberculous affection." His conclusions were that "the common varieties of pulmonary phthisis were to be regarded as due almost solely to various forms of chronic inflammatory changes in the lung; tubercle was to be regarded as a mere occasional and quasi-accidental complication; both phthisis and tubercle were robbed of their so-called 'specific' attributes." He found it "difficult to come to the conclusion that the products (after inoculations) found in rodent animals have any real right to be considered tubercle." This speaker showed, in perhaps an exaggerated form, the tendency which was then so strikingly prevalent with most pathologists to regard nothing as "specific." There existed at that time a widespread dislike, almost amounting to hostility, to the idea of anything being of a "specific" nature, either in pathology or therapeutics. We see this cropping up again and again in this discussion. At that time nothing was "specific," now everything is "specific." Another authority we find also maintaining "that tubercle could not be regarded as the essential specific element in phthisis." He thought that "much of the inveteracy of phthisical lesions would be explained without the aid of any precedent deposit of tubercle." He was disposed to refer the causation of these destructive changes in the lungs to the accumulation in the alveoli of simple, catarrhal products which "accumulated, decayed, and irritated the alveolar wall and set up those proliferative and inflammatory changes which constitute local tubercle, &c."

The veteran Dr. C. J. B. Williams believed that the "consolidation of scrofulous pneumonia and similar low inflammations induce consumption of the lung in the same mode as tubercles" and he was therefore opposed to the idea of unity. Another pathological authority leaned towards the idea of unity, but he would discard the use of the word "tubercle" and he looked upon "the various anatomical changes met with in the lungs in phthisis" as the "result of inflammation." The idea of unity was strongly opposed by Dr. Cayley who would restrict the term "tubercle" to the grey granulations and thought the changes in the lungs in many cases of phthisis as "entirely due to inflammatory processes" and that in some cases tubercles were developed secondarily to inflammatory changes which constituted the primary affection.

In a very interesting contribution to the debate, the late Dr. Moxon ranked himself boldly on the side of unity. "He believed all phthisis was tuberculous" but he thought the "notion of tubercle as a specific growth" had received a serious blow from the results of the inoculation experiments of Sanderson and Wilson Fox, and thus we see this acute observer led astray by the prevailing antagonism to the idea of specificity and by his belief in the results of experiments which proved to be fallacious. He thought the term "fibroid phthisis," unfortunate—"it was nothing more than old phthisis," in which a good deal of fibre was necessarily present; "fibroid phthisis was only phthisis with its age forgotten." This is a view which is now very generally accepted.

From these brief extracts from this debate you may form a good notion of the differences of opinion that existed less than twenty-five years ago amongst eminent pathologists as to the true pathology of phthisis. They show how little finality, definitiveness, and agreement were obtainable from having exclusive regard to the histological characters of the changes attending this disease. As I have already said, it is remarkable how little reference is made in this debate to the infectiveness of tubercle, to which, however, attention had at that time been strongly directed in many quarters, and which fact in the life-history of this disease contained within it the real truth as to the pathology of phthisis.

Before passing away from this stage of our pathological retrospect I ought, perhaps, to summarise the chief conclusions arrived at by Dr. Wilson Fox in the debate as to the nature and origin of tubercle. He had such a tender respect for the opinions of others that there was a certain hesitancy in pressing home conclusions at which he had arrived out of regard for those who upheld the contrary; it was on this account that some complained of a want of clearness in his statements. Charcot, who held the same opinion as to the unity of phthisis, expressed to me his regret that Wilson Fox had not expressed himself with greater clearness and emphasis. Wilson Fox himself characteristically observed at the end of his argument—"There are no subjects in medicine which would, I think, so dispel a spirit of dogmatism and exclusive adherence to one's own opinions as the study of phthisis, on which such differences have existed, and do exist, among the greatest men of the past and present, as may well make anyone doubt the accuracy of his own observations and the justness of his conclusions." The following is the manner in which he formulates the doctrine of unity: "The destructive changes in the lung characterised by the term 'phthisis' are almost invariably associated with, and in great measure caused by, a series of cell-growths which in their anatomical structure and vital characteristics are practically identical in all the forms of the disease." Caseation he regarded as due to the destruction of the capillaries of the new formation, and he recognised that the new growth was capable also of undergoing a development into fibroid tissue. Tubercle he defined to be "a lymphatic overgrowth produced by irritation under special circumstances of anatomical or constitutional predisposition ..... when you give rise to irritation in cases where lymphatic irritability is excessive under these circumstances you may get tubercle. You may therefore get it from a blood state in which the relations of the lymphatics are abnormal, or you may get it locally by exciting inflammation." "The anatomical and vital character of those tubercular growths are distinctive, but they cannot be called specific," but "cases where any close similarity exists between simple inflammation and tubercle are, however, rare, and even then it is a superficial resemblance rather than an identity of structure." "In those acuter forms of phthisis—the so-called scrofulous pneumonia—the process is identical step by step with the majority of the processes that occur in acute tuberculisation, and differs from it only in the extent of pneumonic exudation." "Chronic phthisis is distinguished by the characteristics of induration of the lung ..... the chronicity depending upon induration of those growths rather than on their acute destruction." "Every indurated form of phthisis, most cases of so-called fibroid phthisis of some English authors ..... come under the category of indurating tuberculosis." He denied or doubted the origin of phthisis in catarrhal pneumonia, scrofulous bronchitis, and scrofulous pneumonia. He pointed out that "the products of ordinary inflammation are in the lungs, as well as in the serous and mucous membranes, almost always found co-existing with tubercle ..... the tuberculous growth is something super-added to this, and gives to the pneumonia characteristic features ..... Anatomically, pneumonia is not tuberculous unless that growth co-exists in the alveolar wall."

The great merit of Wilson Fox's conclusions was that they went far to re-establish the unity of nature and origin of phthisical processes in the lungs—they went to disprove the then common belief that pulmonary phthisis could originate in ordinary inflammation, and they disposed of much of the erroneous opinion then existing about "caseous pneumonia," "scrofulous pneumonia," "fibroid phthisis," and the like. The confusion that these terms had given rise to and the false impressions some of them had produced on the professional mind were remarkable. I have known medical practitioners ask the question with regard to an unusually rapid form of phthisis, with extensive diffuse infiltrations, whether one did not think it might be "pneumonic" and not "tuberculous"? and this was asked with the impression that the "pneumonic" form was less virulent and more curable than the tuberculous, whereas it is precisely these so-called pneumonic forms of phthisis, as we

Digitized by Google

know, which are so rapidly fatal. With regard to the real nature of the infective property of tubercle, Wilson Fox was led away from the truth by the results of his experiments on the rodentia, and by the fact that he shared the then prevailing reluctance, almost amounting to actual hostility, to regard anything in pathology as specific. On this point he says, "You may get a tuberculous gland secondary to any common irritation in a predisposed subject ..... any irritation of the tissue may, in the presence of local or constitutional predisposition, give rise to secondary growths diffused or circumscribed which constitute tubercle, and which may be the source of further infection." ..... "Specificity," he said, "is negatived etiologically in every phase of its history except the hereditary tendency, and how far back this reaches it is impossible to say, but that the disease may arise *de novo* under various unhealthy influences none of which can be called specific is a fact which I think no one can deny!" We now know that much of this teaching is erroneous. The idea of the infectivity and transmissibility of tubercle, so little dwelt upon in this discussion, had however taken deep root in the minds of many of the Continental pathologists and between the date of this discussion (1873) and the announcement by Koch of the discovery of the bacillus of tubercle in 1882, a great deal of good work was done in this direction with the effect of preparing men's minds for the great event. I have already alluded to Chauveau's observations in corroboration of those of Villemin. Observing that the infective virus was sometimes found in the fluids of the phthisical, he came to the conclusion that this consisted of very minute particles "imperceptible even under the microscope, inert in appearance, but endowed, in reality, with a singular virulence." Buhl in 1873 and Klebs in 1875 expressed their belief that bacteria were the cause of tubercle, and that they probably existed in the caseous masses. In 1877 Klebs professed to have isolated and cultivated the "monas tuberculosum," but he failed to establish its specific character. Toussaint (1881), Baumgarten and others also discovered microbes which they thought might be the active agents in tuberculosis. Professor Bouchard in 1881 argued vigorously on general grounds that phthisis must be classed amongst the infective diseases, and the next year (April 10th, 1882), R. Koch announced to the Physiological Society of Berlin that he had succeeded in isolating and cultivating the microbe of tuberculosis, and it was thus left to a German to give absolute demonstration of the causal unity of phthisis in all its various manifestations, as had been taught at the beginning of the century, by the great Frenchman Laennec, and this great event may fitly close the strictly pathological part of our retrospect. It is not possible to over-estimate the importance of the results which followed this discovery. The discovery of the true pathology of phthisis has been attended with practical advantages of the most remarkable kind; a flood of light has been thrown on its etiology, and the knowledge of the true nature and mode of propagation of this disease has led to a vast improvement in our methods of dealing with it, both in the way of prevention and cure. This is proved by the striking reduction in the death-rate from phthisis. From 1858 to 1860 the death-rate per million from phthisis was 2565; from 1889 to 1893 the death-rate had sunk to 1512, a reduction of 41 per cent. The recognition of the infective and communicable character of the disease has doubtless had a great share in producing this admirable result.

The methods now adopted for dealing with phthisical sputum, which often swarms with myriads of infective organisms, is an important check to the spread of this disease. It should be—and in many public institutions and private houses is—collected in spittoons containing a solution of carbolic acid or corrosive sublimate or some other disinfectant and subsequently burnt. Pocket-handkerchiefs should also be disused or specially prepared paper ones used, which can be at once burnt. The careful examination into the quality of meat and milk provided for the use of the public has no doubt tended to check the spread of tuberculosis by means of these agents, especially amongst children; whilst the practice of sterilising milk for the use of the poorer classes must have an excellent effect in the same direction. The possibility of the communicability of phthisis from one person to another, in most cases probably through the agency of the sputum, is now well recognised, although at first the evidence in favour of such occurrences was strongly contested. Indeed, I remember hearing a very eminent physician, now dead, publicly state it to be his belief that, supposing the communicable and contagious character of phthisis to be established, it would be a calamity for the public to become acquainted with the fact, and he doubted the propriety of medical men conveying such information to their patients, for he feared lest the distress and sufferings of the phthisical should be increased by finding themselves shunned as objects of danger. Now it appears to me that we have no right whatever to keep from the public information of that kind, and while we have long been urging on the public the necessity of the observance of most careful measures to avoid the spread of the more generally recognised contagious maladies it would be most inconsistent and unjustifiable not to explain to them the degree and extent to which this disease, which carries off a greater number of victims than any other, is infective and transmissible. The public are now pretty well informed on this matter, and I am not aware that phthisical patients complain of receiving less care, attention, or sympathy because of this. One thing I believe the spread of this knowledge amongst the general public has done, and that is to diminish greatly the number of marriages between the phthisical. Much greater care is now observed by the heads of families and others in preventing such very undesirable unions.

I find in the annual health report (1895) of Dr. Boobbyer, the medical officer of health of Nottingham, the following:—"Circulars are now issued to houses in which consumptive patients are known to be domiciled, setting forth the precautions to be observed in order to guard against the infection given off by the patients, and whenever the disease is known to have proved fatal, an offer is made to disinfect the part or parts of the house that have been used by the deceased free of charge. The public response to this offer, which has continuously increased from the outset, indicates a growing appreciation of the necessity for such precaution in the case of this most distressing and fatal disease."

COPY OF CIRCULAR.

BOROUGH OF NOTTINGHAM. PREVENTION OF TUBERCULAR CONSUMPTION.

This disease is infectious, and liable to spread among persons living in contact with those suffering from it.

Where the lungs are principally affected, the spit of the patients contains most of the poison. This should be received into a vessel containing a strong solution of carbolic acid (1 of carbolic to 20 of water), and all washing materials and utensils soiled by the patients should be soaked in the same solution before being washed.

Consumptive patients should always sleep alone.

The rooms of consumptive patients should be aired every day, and disinfected and cleaned at least once a month.

In case of the death or removal of any consumptive patient, the Health Department will undertake the disinfection of the infected house and materials.

PHILIP BOOBBYER, Medical Officer of Health.

Guildhall, Nottingham.

A considerable improvement also in the results of treatment has, I am satisfied, been the consequence of our more accurate knowledge of the pathology of phthisis. The very general adoption of aseptic and antiseptic measures in the treatment of phthisis has, I am satisfied, been followed by far more satisfactory results than we used to get before such remedies were used. No one now doubts the advantage of the open-air method of treating pulmonary phthisis when this can be carried out in suitable localities where the air is aseptic and enjoys at least a relative freedom from the presence of germs. The systematic employment of antiseptic inhalations and the internal use of such agents as creosote and guaiacol have no doubt some influence in checking the diffusion and diminishing the virulence of the infective processes in pulmonary tuberculosis. The course of the disease is retarded and time is thus gained for the establishment of indurative changes in the tuberculous infiltrations, and this is the natural method by which phthisis is arrested and cured.

But it is not my purpose to-day to enter upon any therapeutical discussion, it has simply been my desire to call your attention to what I think is a remarkable chapter in the history of medical pathology; a chapter which shows how dogmatic and assertive scientific men may become and into how great errors they may fall when they trust too implicitly to certain favourite methods of investigation and follow too partially their own preconceived notions. There is always some risk of fallacy if we attempt to determine the true nature of a series of phenomena when we only look at a limited part of them. For instance, the inability to recognise the specific nature of tubercle, and the tendency to positively deny it

which appears so frequently in the discussion to which I have referred, had no real foundation in the thing itself. Pathologists rejected this very precise and definite view, which Laennec had asserted and Villemin had gone far to establish, for such indefinite ideas as are to be gathered from the words "inflammation," "irritability," "irritation," "disposition" or "predisposition" and the like. What, in the shape of precise knowledge, do such terms convey? What was there so fascinating in the word "inflammation" that it should have been adopted as able to cover all the facts in the life-history of phthisis? What exact information as to causal relations does it convey to our minds? Why, again, was there such great hostility manifested to the idea of specificity? It seems to me very difficult to find satisfactory answers to these questions.

I have been able, I think, to show into what errors these tendencies led some of the most able, and certainly some of the most laborious, pathologists of our time. With the new and exact methods of experimental research which we now possess we seem to be able to arrive at conclusions more definite, more certain, and less hypothetical, and we use terms less vague and indefinite, but even with those methods at our disposal we should learn from the past the need of great caution against forming too hasty or too positive conclusions in all subjects which present any scope for controversy. I think I have shown how easy it is even in careful scientific researches to make many false steps; let us then at all times walk circumspectly and warily.

MOTOR AND SENSORY APHASIA (WORD-DEAFNESS, WORD-BLINDNESS, AND MIND-BLINDNESS).[1]

BY ALFRED MANTLE, M.D. DURH., M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL HALIFAX INFIRMARY.

ALTHOUGH in each of the following two cases of aphasia there was a combination of motor and sensory disturbance, it is chiefly on account of the sensory derangement of speech that I have recorded them.

CASE 1.—The patient was a well-built man, aged forty-one years, who a little more than nine years before had some slight epileptiform convulsions; after one of these attacks he had paralysis of the right arm and leg and was aphasic. The aphasia, however, was not so lasting as in the attack I am about to describe, for he went to work in fourteen weeks, having recovered speech completely and the power of the right arm and partial power of the leg. Five years afterwards he had another, but much slighter, attack, lasting a fortnight, when speech was again affected and paresis of the right side occurred. His health receiving a great shock he gave up the very active work he was engaged in and had a long rest. He practically recovered and worked fairly hard again, but complained of headaches and giddiness. The viscera were healthy, and there was no evidence of syphilis. The attack I now relate commenced on Oct. 29th, 1892, with no marked premonitory symptoms. He was gloomy the day before, and shut himself up, and drew some curious pen-and-ink sketches, but he did not complain of his head. He retired to bed, and his wife roused him early next morning, as he had an appointment, and she discovered that he was perfectly conscious, but speechless; she noticed that the tongue was drawn to the right side, but the features were quite straight. There was slight numbness all down the right side, but power enough in the hand to write slowly. I was called in to see him at 8 P.M. I found complete motor aphasia—i.e., he had lost all power over the motor part of speech, and the only sounds he could utter were "o" and "a" fairly well and "u" indifferently. The tongue could only be partially protruded and deviated to the right, and the lips did not move. There was slight loss of power in the right leg, but less marked loss of power in the right hand. He could, however, write slowly with this hand, and he asked me several questions in writing which were intelligent and written correctly. He complained of the back of the head being painful and of having a burning sensation in that region. During the first week he was very emotional and easily excited, and at the end of the week he was very drowsy and difficult to rouse, and the paralysis of the right side was complete both for motion and sensation. There was marked rigidity of the right hand and arm, and the thumb was firmly contracted into the palm. The left hand was very tremulous and deficient in power, and sensation was diminished on the left side, but not so markedly as on the right. A curious spot of hyperæsthesia was discovered by the nurse on the inner side of the right knee, this being so sensitive that if touched ever so lightly he would spring up in bed and suffer agonising pain. He was now in a very sensitive condition, for the movement of lifting him up in bed to change his position had an extraordinary effect upon him and produced a drowsy and more or less unconscious condition which was very marked during the whole of the second week. Motor power, however, on the left side was practically normal and he could write slowly with the left hand. From the third week he gradually improved, gaining steadily more power in the right leg and arm and recovering sensation. He was much interested in all that was going on, reading daily papers and discussing topics of the day by writing with the left hand, for he was very little, if any, better so far as his aphasia was concerned. There was, however, during this period of motor recovery a good deal of sensory disturbance, particularly from the eighth week to the eleventh, when another condition developed—namely, that of sensory disturbance of speech. It was noticed that he was slightly deaf on Jan. 19th, which increased during the day and became complete on the following day. Dimness of sight was also observed, and he suffered a good deal of pain in the head. Next morning he could not read writing, however large, but could read words composed of large printed letters, but these were only of use until 3 o'clock in the afternoon, when they could no longer be seen. On the following day sight and hearing were gone on both sides, but a lighted taper passed before his eyes produced a pupil reflex. The ophthalmoscope showed the fundus of both eyes to be normal. There was a good deal of difficulty in swallowing. He had a fixed staring look, straight out, and was always plucking at the bedclothes with the left hand, a meaningless sing-song being heard at intervals. He now continued to be deaf and blind for ten days, and could only recognise his wife and nurse by the sense of touch, feeling their hands and articles of dress. On the eleventh day he showed signs of delight when the blind was drawn up and light admitted, and he could then recognise the difference between the hands of his wife and nurse. He was still deaf to words, but could hear sudden sounds. On the twelfth day he heard and seemed to recognise his own name, and he also noticed details in the dress of those about him. On the next day he saw colour in some tulips placed before him, which evoked grunts of satisfaction. Pointing to his ears and eyes he asked with his finger on the coverlet why he was deaf and could see so badly. Fourteen days after the loss of hearing he heard sounds at a distance, a dog barking, whilst he was comparatively deaf to sounds at his bedside, and on the following day he asked by making the outlines of the letters on the coverlet of the bed with his finger why he heard sounds (at the same time pointing towards the next house, where a piano was being played), yet could not tell what was said by those about him. He had now extended vision, pointing to pictures on the wall facing him, but the field of vision was very limited, and it was found he had right hemianopsia. He continued to be very deaf to ordinary word sounds, but the experiment of whispering the word "better" slowly in the right ear was tried. He heard it, and immediately began to write with his finger on the coverlet the whispered word, and showed signs of gratification. The same word spoken in natural tones produced an expression of pain and bewilderment. His mind continued to be very clouded, and he was unable to understand day from night or the time of day. Feb. 9th was the last day he made known his thoughts by drawing with his finger the outlines of letters forming words. He had during the day thought out and written a number of questions and was somewhat exhausted. His left hand (which he could alone use) was said to be rigid in the evening, the rigidity passing off very soon, but next day his sight was very much worse, and all hearing had gone again. He now had a slight attack of influenza, which was prevalent at the time. He could no longer form the outlines of letters, and the only way he could express his thoughts was in pantomime. He, like an uneduca'ed deaf-mute, made pictures in the air to express his

[1] A paper read before the Medical Society of London on Nov. 23rd, 1896.

Digitized by Google

wants, and his wife understood his drawings in a wonderful manner. Wishing for a chop, he drew the shape in the air. Wanting milk and soda water, he pointed to the sheet for whiteness, and drew in the air the shape of a soda-water syphon. Before losing all sight he had enjoyed seeing and arranging a bunch of lilies of the valley. He evidently remembered this and drew in the air the shape of lilies of the valley, arching the stems and dotting them with flowers. His wife understood and brought the flowers to him, when he was quite satisfied and arranged them with care. His sight again came back, but he was still suffering with right hemianopsia. Although an omnivorous reader when well, he did not recognise when tried either letters or figure symbols, and when a paper was given him he turned it upside down, and by gesture asked why it was given him. There were now (the end of February) distinct signs of recovery from motor speech, and he uttered his first word, "better," distinctly enough to be understood. The right leg and arm also had much more power, but the arm was exceedingly sensitive to touch. He understood whispered language more easily, but he was unable to recognise words in the ordinary strength of tone. Although deaf to words, he interpreted tones and gesture so well as to be conversant with much that happened. In March mind-blindness was most marked, though he had not so much difficulty in remembering objects as persons. His aunt, to whom he was very much attached, was allowed to see him. He did not recognise her, but after she had left the room he drew, with a pencil in the left hand, the house in which she lived, with the road to it—the garden and the dog at the gate—which was a very fair description of her abode. During this month his deafness gradually improved, but he was more deficient on the left side than on the right. The sense of smell was impaired on the left side. He saw better, but had yet word-blindness. He was able to articulate more and used and understood more words, but he made use of pantomime as well. The very sensitive spot on the inner side of the right knee, which had remained so all these months, could now be touched, he having asked the nurse to lay her hand lightly upon it for trial. He tried to count, but it was difficult, especially on more than one hand. He soon became more inquiring and asked "what was it he used to do." When told "to paint" he remarked "what was that?" Upon pursuing the subject he was told he used to read books, when he replied "that sounded like it." He was now getting up daily and was greatly interested in building with dominoes. He took a little more interest in things, but at the end of March (five months after the attack commenced) he still had forgotten that he ever was a painter. He was one day anxious for a certain picture to be brought to him which as a matter of fact he had painted, but when asked if he painted it he emphatically stated no, but that he remembered seeing a man paint it. He was very anxious to know what a book was. In April he noticed the lettering upon half a crown, given in his hand, when he asked to have it read to him, repeating each letter after the nurse and committing them to memory and comparing their form with other letters; he asked if these were what were contained in books. He could not remember his own surname, and when told his wife's surname he indignantly denied it and uttered her Christian name. He was now taking great interest in looking at pictures in illustrated papers and was very critical. He was able to remember letters and words which he had been told a few days before, and it was interesting to notice the aid that the fingers of the left hand were to his memory. If he wanted to remember a thing he looked hard at his left fingers, and, as he remarked, he saw it there in a short time, but often after much puzzling. The patient's condition from this time gradually improved. He was able to understand word symbols more readily day by day, and he could read. He would repeat a word again and again after following the outline of each letter, and having been told what the letters spelled. He often employed a circumlocution of more general words instead of the special word he could not revive in his memory, and instead of asking for "a pencil" he would ask for "something to draw with." His great trouble was that he had forgotten so much. His mind-blindness did not improve, and he could not recollect his most intimate friends when they called to see him. Neither could he recognise paintings which he had spent a great deal of time over, but little sketches which had cost him very little time and thought he could recognise as his work. In August he had partially recovered his loss of power, but he had still right hemianopsia, and his motor speech was very indifferent. His friends attempted to get him into the air, after which he seemed very much worse, for the movement upset him considerably. Early in September he had been reading, and was very cheerful before taking his afternoon sleep, but when he awoke he was found to have a dazed look and to have lost all power of the right side. On the following morning I found hearing and sight completely gone. The tongue could not be protruded from the mouth, but deviated to the right. Swallowing was difficult, and there was also loss of sensation and power of the right side. He was completely deaf to words, even when whispered, but he had painfully acute hearing for sounds. There was one marked difference in his condition now from that in his previous attack, which was that he had always been able to make known his various wants by writing with his finger the outlines of the letters upon the sheet, which power he lost in the previous attack, when he was reduced to pantomimic signs. The word-deafness and loss of sight continued for four weeks, but he had right hemianopsia for several months afterwards. While deaf and blind to words, as well as having complete paralysis of motor speech, he expressed a wish to make his will, and made his wishes known by forming the outline of the letters on the sheet of the bed. He also made his lawyer and wife understand that when they meant "yes" they were to tap his hand and when "no" they were to cross it. To satisfy him the will was executed, and with his left hand he very badly wrote his signature. He now gradually recovered from word-blindness and very slowly regained power in his limbs, but the motor part of the aphasic condition was very slow in recovering, for he was unable to speak until the following April, when he commenced and rapidly regained speech, it having been absent since its partial recovery for thirty-two weeks. On getting downstairs he almost at once commenced to strum on the piano, and it was noticed that he had no difficulty in reading music. This test, however, had not been tried when he was word-deaf. At the end of the second year he was able to walk slowly on crutches. His zest for painting returned and he found the greatest pleasure in sketching from nature while he was convalescing. His mind was a complete blank with regard to paintings he had done before his illness. His power of motion steadily returned, and at the end of the third year he could dispense with his bath chair. It was very curious how, in the early period of his convalescence, movement of the body—i.e., to another room—brought on the sensory disturbance of speech for perhaps twenty-four hours. This occurred on three or four occasions. Four years have now elapsed since the attack came on, and I quite recently had a chat with the patient in his studio. He told me that he had tried hard to paint during the past year, but he was so disgusted with his work that he had practically given it up. To my uncritical eye his work looked very passable. He said, however, that his difficulty was in trying to remember how he used to do it, and when he found he was doing the thing wrong he was so dissatisfied with his efforts that he had ceased to make further attempts. He could, however, do pen-and-ink work exceedingly well. On asking him if he remembered painting the pictures about his room he said he did not, but he still thought he saw another man paint one of them. He described himself as being a better judge and more critical than ever he was before, but no workman, and this was not through want of muscular power, for that he had quite recovered. He has been colour-blind ever since he was fifteen years of age, his difficulty being to distinguish green from red. On inquiring if this was any worse or was in any way explanatory of his failure he said it was not, but if anything he thought the condition was a little better. He had always had an ambition to become an author and had written considerably; but he told me that he now found this work most difficult, his power of concentration being limited and thought slow. He had a very good vocabulary, however, when talking, and was never at a loss for a word, though there was sometimes an occasional hesitancy in pronunciation. Contrary to Lichtheim's experience, the sensory aphasia in this case of total aphasia cleared up before the motor.

CASE 2.—Another case of sensory and motor aphasia came under my care at the Royal Halifax Infirmary in the month of February, 1896. I had seen this patient five years before in consultation with Mr. Steele, of Halifax, when he was suffering from paralysis of the extensors of the left forearm, which had come on quite suddenly. There was no disturbance of speech at this time. He was said to have recovered from this attack. Two and a half years afterwards he had an

Digitized by Google

epileptiform seizure, and partially lost the use of the right leg and foot, from which he recovered, but he had subsequently at intervals slight fits, one of which ushered in the present condition, and was attended with twitching of the right side of the face. There was a clear history of syphilis made out before, but the condition of the patient now was such that he could give no account of his illness. "I really cannot tell you, I am sure, just now," was his answer to every question put to him, and it was evident he had no comprehension of word language. He read with great difficulty figures and could not read printed matter accurately, but could make out some letters. He could not recognise a bell on the table, but could recognise a watch and a knife. When a water-pipe was pointed at he could not say what it was, but said "hot." Apparently there was no defective eyesight, but an exact perimeter tracing could not be taken on account of the patient's inability to comprehend what was wanted. The motor part of speech was good and there was no paralysis, and his gait was normal, and so were the organic reflexes. He looked in good health and apparently was always in a good humour, readily pleased, but not in any way emotional or childish. On further examining the aphasic condition he seemed to have a more or less complete comprehension of the uses of the objects shown, but could not always give the correct designation. Some things shown he remembered easily and could pronounce their names, others he could not name, but if he thought for a time he sometimes gave the correct name or a similar sounding word, or substituted a round-about phrase as an equivalent. Occasionally when taken suddenly he seemed to answer instinctively and generally correctly. A pencil he knew the use of, but could not name. A pen he called "pea," then pen. A knife and fork and book he knew. A cork he knew, but he called a bottle "brot," and medicine he could only pronounce partially. A key he called "lock," recognising its use. He knew his own name, but occasionally transposed the two parts. In the identification, then, of objects shown he occasionally used the association of ideas. Water pipe he called "hot," and the key "lock," but mispronounced some words. On investigating the visual sense in reading printed or written matter he was found to be much more incorrect. He could read figures accurately, though with some hesitation in some cases. When spelling out, letter by letter, printed words he was very incorrect, and did not always give the same interpretation on two consecutive occasions, while in time he might stumble into a correct reading. When reading and pronouncing words there were similar hesitation and inaccuracy, while there was often an approximation to the sound—e.g., he called London "Luddenden" (the name of a local village), after considerable doubt. His own name he was able to read correctly. On testing his capacity for repeating words there was evidently a degree of inability to recognise certain words and phrases. "What is your name?" he replied to correctly. "How old are you?" he could not understand. Certain words he was deaf to and could not repeat, and through the word-deafness he was unable to comprehend and allowed his mind to dwell on one or two stock phrases, which were always ready, and from which it was difficult to divert his attention. His memory was very defective and he could not say where he lived or the town he lived in; but the word-deafness might account for this. Neither could he say how long he had been ill. On testing his writing from a copy it was found that he made the same errors as in spelling, but did not make the same blunders twice. At times his writing was quite clear, whilst at others it was quite unintelligible. He could write his name, but sometimes transposed it and sometimes left out letters. He could copy figures more accurately than letters. His condition seemed to improve a little, and remained bright and cheerful. He was able to talk and answer simple things correctly, and his memory was a little better. Early in the morning of March 24th he went to the ward lavatory, and was found afterwards in an insensible condition. Apparently he had had a fit, but was quite unable to speak. There was complete paralysis of the right leg, the limb being quite flaccid and paralysed, with rigidity and contracture of the right arm. The eyes and face were unaffected. He could only partially comprehend what was said to him, and could make no response. He gradually recovered power in the leg and arm, and made attempts at speaking, and could utter one or two words—"very nicely," "yes," "getting on," and a few others—and seemed to comprehend more what was said, but his attention was very easily over-tired. On May 8th he had another attack, when he was quite speechless and collapsed. The nurse had observed some twitching of the muscles of the right side of the face when he awoke; he then lost the power of the right arm, but the leg escaped. The condition of paralysis was succeeded by one of rigidity. There was difficulty in swallowing, and the patient was very irritable. He seemed to understand a little more what was said to him in a few days, but recovery was very incomplete, for there was no return of intelligible speech, and there was complete loss of power over the right hand and partial loss of power of the right leg. He became very restless—constantly attempting to get in and out of bed—and was so noisy that we could no longer retain him in the infirmary. His condition is very pitiable at the present time; he cannot understand anything said to him, has complete motor aphasia and right hemiplegia, is very emotional, and presents all the symptoms of cerebral softening.

Although motor speech has been involved in both of these cases as well as sensory, as I have said before, I have brought them forward chiefly on account of them being good examples of sensory disturbance of speech. In Case 1 it is remarkable how compound was the aphasic condition, and it is most probable that there was thrombosis of the Sylvian artery, for all the cerebral centres concerned either in the expression or the interpretation of speech are situated within an area supplied by this vessel. The centre for motor speech (the posterior part of the third frontal convolution and the lower part of the ascending frontal convolution on the left side) was first affected, and the ascending frontal convolution containing also the cortical centres for the movement of the tongue and lips accounts for the early loss of these movements in this case. The part of the brain concerned in the sense of hearing was next affected, which is the posterior half of the first temporo-sphenoidal convolution on the left side. When this region is diseased there is often transient deafness in the opposite ear. The fact observed that he could hear a whisper and understand the word when whispered very softly and slowly is one I find no record of, but points, I think, to over-stimulation of the centre by the ordinary voice, preventing perception of sound characters. The hearing of both ears went simultaneously, but the right, or that on the opposite side of the lesion, was the first to recover. In word-blindness a lesion of the first temporal convolution is found in the majority of cases. The hemianopsia was probably due to involvement of the occipital lobe, for the pupil still continuing to respond to light supports Wernicke's suggestion that the symptom is then due to a lesion in the occipital cortex. The amaurosis which has been present in both attacks is probably cortical also, and is difficult to explain. The optic nerve always looked healthy. Mind or object blindness was part of the visual disturbance. It has been produced artificially by Munk in dogs by extirpating parts of the occipital lobe. Loss of smell, which was associated with the sensory aphasia, is thought by Gowers to be due to softening of the root fibres at the commencement of the fissure of Sylvius. I have not mentioned the fact before, but this patient had visual hallucinations, which Professor Henschen in his work, "The Pathology of the Brain," directs attention to as likely to trouble a patient with homonymous hemianopsia when that symptom is of cortical origin. He said he could always see in the blind half of the field of vision a man at the back of his head holding two lighted candles. Bastian has strongly pointed out that lesions in the posterior parts of the brain are more apt to produce hallucination than lesions in the middle or anterior parts. The amount of sensory disturbance was very remarkable in this case, and might have suggested, at an early period, a purely functional origin, but, as Wyllie says, "the very existence of word-deafness or word-blindness in any case should suggest an organic rather than a functional cause."[2]

In Case 2 there is not much to note except that the sensory aphasia came on first and long before the motor condition; also that there was an absence, as far as could be made out, of any hemianopsia with the word-blindness. The probable cause in this case is thrombosis, which may be proved in a short time, as the patient is now *in extremis*.[3] An important question in connexion with aphasia is its influence on testamentary capacity. In Case 1 the patient, as I have related, made a will and signed it. In concluding

this paper I have to thank various writers—Broadbent, Gowers, Wyllie, and others—for many suggestions, not forgetting my teacher, Hughlings Jackson, to whom I am indebted for any interest I take in this subject, and Dr. Maxwell, senior house surgeon to the Halifax Infirmary, for assisting in the note-taking of Case 2.

Halifax.

A CASE OF EXCISION OF THE SCAPULA FOR LARGE CYSTIC SARCOMATOUS GROWTH.

BY CHARLES A. MORTON, F.R.C.S. ENG.,

SURGEON TO THE BRISTOL GENERAL HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN AND WOMEN; PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, AND OF ANATOMY TO THE ACADEMY OF ARTS.

A WOMAN, aged thirty years, came under my care on Nov. 18th, 1896, with a swelling in the position of the left scapula of four months' duration. There had been rather severe pain in it at times. The swelling was as large as the patient's head, smooth and round, with enlarged cutaneous veins over it. There was a freely fluctuating area, the size of the palm of the hand, in the centre of the swelling. The body of the scapula was buried in the swelling, and what seemed to be the angle was pushed much nearer to the spine than normal. There was a projecting mass of considerable size beneath the teres muscles, and the growth extended into the inner portion of the supra-spinous fossa, round the base of the spine. The acromion process and its junction with the spine and the region of the glenoid fossa seemed free from growth, and movements in the shoulder-joint were quite free. The whole mass of growth with the scapula was movable on the chest-wall beneath. An exploring syringe withdrew clear serous fluid from the fluctuating area in the centre of the swelling. It seemed probable that there was a cyst in a mass of sarcoma growing from the scapula.

I operated on Nov. 25th. Precautions were taken by the administration of brandy and the arrangement of hot bottles about the patient, before the operation began, to guard as far as possible against severe shock. An exploratory incision was then made into the cyst, and it was found to be part of an enormous sarcomatous growth. Excision of the scapula was therefore proceeded with. The exploratory incision was continued upwards and downwards along the vertebral edge of the mass for eight inches, and outwards over the spine and acromion as far as the acromio-clavicular joint, and the flaps turned up and down. I then divided the levator anguli scapulæ and rhomboids and found that the vertebral border and angle of the scapula had disappeared in the mass of growth. The attachments of the deltoid and trapezius to the spine were next divided; I then found the growth extended for an inch above the upper border of the bone, but it was at this point well encapsuled. In separating the mass here, I was not able to recognise the supra-scapular artery, nor did a vessel of any size bleed. The supra- and infra-spinatus muscles did not appear to be infiltrated as they approached the shoulder-joint. I therefore cut them through about an inch from the joint, and found the section healthy in appearance, and as the growth did not in any way encroach on the glenoid cavity I proceeded to saw through the spine at its junction with the acromion, and then through what has been called the "surgical" neck of the scapula—through the depression between the supra-scapular notch and the axillary border just where the triceps is attached. This section completely detached the head with the glenoid fossa, and the shoulder-joint was not opened. The coracoid process was left attached to the head. This division of the bone brought the subscapularis into view and I divided it. The body of the bone with the mass of growth was now only attached by the teres muscles and the serratus magnus, which were finally divided. The subscapular artery was clamped before division. An enormous number of small bleeding points were tied, and often between one and two dozen forceps were on the vessels at one time, but the patient lost very little blood considering the extent of the operation. She looked pale at the conclusion of the operation, and two drachms of brandy were given hypodermically, but she did not suffer severely from shock. The pulse was then only 106. Digital pressure was made on the subclavian artery in the posterior triangle before I began to divide the parts in the neighbourhood of the subscapular artery. Although the most scrupulous care was taken with every antiseptic detail the wound suppurated. This was almost certainly due to auto-infection, as she had a sinus leading to bare bone in the other arm; but during the healing, which was protracted, she gained flesh. There is now (July, 1897) no sign of any recurrence. The head of the bone can be rotated freely in the glenoid fossa. All movements of the forearm and hand are normal; the biceps and triceps act well. She can raise the arm a little more than to half a right angle, but only to half a right angle by means of the deltoid; beyond this the trapezius draws up the outer end of the clavicle, and with it the arm. There is no power of external rotation in the shoulder-joint. The acromion process became tilted, so that the upper surface no longer looked upward, but only backwards. The arm is a very useful one.

The mass of growth, on examination after removal, in some parts presented the appearance somewhat of fat, but was more gelatinous, and in others was white and firm. In the centre it was infiltrated with serum, and broken down into the cystic cavity which was tapped with the exploring syringe. Communicating with this cyst was a larger one, also formed by degeneration of the tumour tissue. The growth had destroyed the body of the scapula to a very large extent only portions of the bone were found as small thin plates scattered through it. The angle and vertebral border had quite disappeared. The subscapularis, and the infra-spinatus and supraspinatus muscles, except towards their insertions, were replaced by growth which was only covered by the thickened and infiltrated supra- and infra-spinatus fasciæ and the layer of fascia over the subscapularis. The origins of the teres major and minor were extensively infiltrated. Microscopic sections show a tissue composed of small round cells with large areas of degeneration, in which all structure is lost, and here and there amongst the round cells a few imperfect giant cells.

That it is unnecessary to remove the whole bone for even periosteal sarcoma seems now generally agreed upon by surgeons, provided that the section of the bone is made well away from the growth, for if this is done recurrence in the lungs is more likely than recurrence in the portion of bone which is left. I operated on this principle in this case, dividing the bone and muscles everywhere thoroughly beyond the limits of the growth, but not removing the whole bone. It would have taken longer to disarticulate at the shoulder and acromio-clavicular joints and dissect out the coracoid process, and, moreover, the retention of the head and glenoid cavity with the coracoid must add considerably to the utility of the limb. One objection that has been raised to leaving part of the scapula—that the cut arteries tend to retract behind the portions of bone left and are more difficult to secure—cannot, I think, be entertained—at any rate, when only the head and coracoid process are left.

Clifton, Bristol.

SOME UNUSUAL CASES.

BY HENRY LEE, F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

CASE 1.—Some years ago, whilst on a visit at West Ilsley, where there was no resident medical man, I was asked to see a boy, who, with others, had been trying a chaff-cutting machine. By some means or other he got his arm in front of the blades whilst the machine was in action. Immediately below the left armpit there was a gaping wound down to the bone. In this the open mouth of the lower extremity of the divided axillary artery could be plainly seen. The boy was faint and frightened, and there was no bleeding then to signify. Having a pocket-case with me the artery was tied and the wound closed. In this case the nerves were doubtless divided. The power of moving the arm had permanently gone.

CASE 2.—A patient who had worn a bivalved tracheotomy tube for a long time presented himself at St. George's Hospital. The shield of the tube had become detached, and the two valves had fallen into the trachea. These were removed separately by a curved pair of forceps.

CASE 3.—Soon after the introduction of the fourpenny-

Digitized by Google

pieces a boy playing with one got it into his trachea. He was placed face downwards over a counter. One person held his heels and two others lowered his head. He soon became blue in the face and had to be restored to the upright position. This experiment was tried a number of times and always with the same result. After some delay this patient went to St. Thomas's Hospital, where one day he went suddenly to the watercloset and was sick. A metallic chink on the pan of the watercloset was heard and there were no further symptoms. The fourpenny-piece was not recovered.

CASE 4.—In Mr. Brunel's case, as is well known, he constructed a revolving apparatus, by means of which he could, when attached to it, be inverted without any physical exertion. The result was the same as in the last-mentioned case. The spasm of the glottis necessitated the return to the erect position. This was often tried, but ultimately with no better result than my "counter" arrangement. At length Sir B. Brodie opened the trachea and Mr. Brunel was placed on his revolving apparatus, and the half-sovereign, which had passed into the trachea, came out of his mouth. I have some reason to know that there was a general impression that the half-sovereign came out of the opening which Sir B. Brodie had made. The explanation, I believe to be this: When Mr. Brunel was inverted, the coin, as at other times, produced a spasm of the glottis, and prevented any air entering the lungs by the natural channel, but the patient was able to breathe through the artificial opening until the spasm relaxed. At all events Mr. Charles Hawkins, who assisted Sir B. Brodie, told me that he received the coin in his hand from Mr. Brunel's mouth. After a time it was found that Mr. Brunel had albuminous urine, and it was supposed that this indicated disease of the kidneys. A consultation was held at Sir B. Brodie's house. There were present Sir B. Brodie, Dr. Owen Rees, Dr. Seth Thompson, and myself. The general opinion was that Mr. Brunel ought to go to Egypt. I ventured, however, to remind Sir B. Brodie that when I was his clinical clerk at St. George's Hospital we had notes of cases in which there was albuminous urine and where there was no disease of the kidneys. Mr. Brunel went to Egypt, accompanied by Dr. Seth Watson, a personal friend of my own, and for some time physician to the Oxford Infirmary, who, as I had subsequently reason to believe, did not pay much attention to the condition of the urine. Mr. Brunel returned in sufficiently good health to undertake the building of the *Great Eastern* steamship, which he accomplished without difficulty. After the lapse of some months he became insensible to external impressions and lost the power of speech. Sir B. Brodie subsequently remarked that he had never known a case in which the power of speech was entirely gone that had recovered. After death the kidneys, upon section, showed no visible signs of disease. There was about half-way down an intussusception in the right ureter, evidently of long standing. The invaginated portion had assumed the appearance of a small tumour constricted at its base. It was as red as the ripest cherry. This left no doubt in my mind as to the origin of the albumin which had so frequently been found in the urine. The convolutions of the brain appeared compressed, but there was no effusion of blood or serum. The rings of the trachea, which had been divided, were found united by cartilage.

Queensborough-terrace, W.

A CASE OF ATROPHIC CIRRHOSIS WITH ASCITES FOLLOWED BY A LARGE CYST OF THE LIVER; WITH SOME REMARKS ON THE QUESTION OF DIAGNOSIS.

BY W. C. DEVEREUX, M.A., M.B. CANTAB.,
SURGEON TO THE TEWKESBURY HOSPITAL.

AT the beginning of March, 1896, I was consulted by a woman, aged forty-four years, who had been ailing for about a month, complaining chiefly of great progressive weakness, sickness, anorexia, diarrhœa, and a great increase in the size of her abdomen. She had previously been a perfectly healthy woman, moderately stout, but had lately been losing flesh. Catamenia had been regular until the commencement of her illness, when they ceased altogether. The diarrhœa occurred from four to eight times a day, the stools being semi-fluid, very offensive, and grey or white in colour. The urine was scanty (sometimes not more than four ounces in the twenty-four hours even when there was no diarrhœa), acid, thick and highly coloured, with abundant urates and a trace of albumin. The tongue was thickly coated, and there was slight jaundice. The heart sounds were weak and there was a soft mitral systolic murmur. The pulse was very feeble and rapid (110). Both lungs were slightly œdematous at their bases. The abdomen was enormously distended with ascites, which prevented an accurate marking out of the liver, which was apparently much contracted. There was the usual etiology of atrophic cirrhosis. On consultation with Dr. Hayward, of Haydock, the case was diagnosed as one of atrophic cirrhosis of the liver. We decided not to tap for the present unless there was any increase in the œdema of the lungs. The patient was put on a liquid diet with no stimulants. She was given one-twelfth of a grain of subchloride of mercury and one grain of powdered boracic acid three times a day, and a mixture containing eight minims of tincture of digitalis, three grains of iodide of potassium, and compound infusion of gentian to one ounce three times a day. On March 19th, as the patient was making no progress (except a slight decrease in the diarrhœa) and the œdema of the lungs had increased, I resolved to draw off the ascitic fluid. This was done by means of a Southey's tube and seventeen pints were drawn off. The liver could now be accurately defined, and the superficial dulness was found to extend on the right side from the seventh to the eighth rib in the mid-sternal line in front and from the tenth to the eleventh rib behind. No dulness could be detected either in front or behind on the left side. The beneficial effect of the tapping was marked on the very next day, when as much as two pints of clear urine, free from albumin, were passed, and three days later bile reappeared in the motions, which were more formed and passed only once or twice in the twenty-four hours. The pulse improved (80) and the mitral systolic murmur and the œdema of the lungs disappeared. There was no sickness and the appetite improved. The increase in strength was remarkable, and in a fortnight the patient was able to sit up in a chair. On April 3rd the patient began to complain of a great deal of flatulence and there was some slight diarrhœa. As the pulse was not so good the mixture was changed to five grains of tincture of strophanthus, three grains of iodide of sodium, ten grains of bismuth salicylate, ten grains of benzo-naphthol, and fifteen minims of compound tincture of cardamom, which checked all the symptoms. About April 15th the patient had not been so well for three or four days, and complained of a feeling of fulness in the left side and a catching pain when she took a deep breath. On examination I found that the liver dulness on the left side extended from the seventh rib to two inches below the costal margin in the mid-sternal line, where the thickened edge of the liver could be felt. There was no increased dulness behind or on the right side. By the 22nd the dulness had extended down to the level of the umbilicus, and there was a large protuberance of about four inches in diameter, over which there was distinct fluctuation, the lowest point of fluctuation being about two and a half inches above the thickened edge of the liver. I withdrew a small quantity of fluid with an exploring needle, and obtained a brown semi-transparent fluid, highly albuminous (one-third), and containing chlorides, liver cells, abundant leucocytes, fat globules, acicular crystals (? tyrosin), and granular débris. There were no hooklets or cancer cells. On May 1st the dulness had extended on the left side into the pelvis and above to the second rib in front and to the upper border of the scapula behind. There were no breath sounds except at the apex. On the right side the dulness extended in front from the sixth rib to two inches below the costal margin, and from the eighth rib to the costal margin behind, and all over the right lung the breath sounds and resonance were normal. During the short time from the first symptoms of pain and fulness (April 15th) the increase in the weakness and emaciation was extremely rapid, so that the patient was little more than skin and bone. The pulse was very feeble (130) and at times scarcely perceptible. The symptoms, in spite of the negative character of microscopical examination of the fluid, seemed to point to malignant disease, probably sarcoma. The state of prostration was such that when Dr. Hayward again saw the patient with me on May 2nd there did not seem

Digitized by Google

the faintest hope of her rallying again. We came to the conclusion that it would not be advisable to attempt aspiration, both on account of the extremely critical condition of the patient and the fear of hæmorrhage into the cyst. About a fortnight later the patient rallied slightly, and the enlargement showed no further signs of increasing. There had been occasional slight shivering fits, with the temperature running up to 101° F. On June 11th I inserted a Southey's tube into the area of fluctuation and withdrew three and a half pints of fluid. This was examined by Dr. Hayward, Dr. Robertson (medical officer of health of St. Helens), the Clinical Research Association, and myself. It was a dark brown, semi-transparent fluid, of specific gravity 1015, containing a large quantity of albumin (one-third), chlorides, no sugar, and was faintly alkaline. On microscopical examination there were pretty perfect nucleated liver cells, numerous fat globules, leucocytes in progress of disintegration, acicular crystals, and masses of bile-stained tissue. There were no cancer-cells, hooklets, or fragments of hydatid membrane. There was considerable improvement after the removal of the fluid, and the patient's strength increased. The emaciation, however, continued much the same in spite of the enormous appetite the patient developed. The temperature still ran up towards evening to 100° or 101°, and was unaffected by quinine. The morning temperature was normal. The stools were occasionally white, but always got back their proper colour on the administration of small doses of calomel. The liver dulness three days after tapping extended on the left side in front from the fourth rib to the costal margin and behind from the angle of the scapula to the costal margin. On the right side it extended from the sixth rib to the costal margin in front. The patient was able to be out of bed again by July 24th, though the liver had again begun to enlarge. By Aug. 12th the liver had again attained its former large dimensions, so I repeated the tapping, again drawing off three and a half pints of fluid. The fluid differed somewhat from that on the first tapping, being of a dirty white colour and non-transparent, and containing more pus cells, but no liver cells or bile-stained tissue, and was of specific gravity 1015. The report of the Clinical Research Association was as follows: "We could find no evidence whatever in this fluid of malignant growth or hydatid disease. It was of exceptional nature chemically, containing neither bile pigments nor bile salts, but somewhat abundant fats and crystals of fatty acids. No cholesterin could be found. The suspended matters were, in fact, composed of broken-down pus cells and fats." The next day the growth had receded to within an inch from the costal margin, and in a week had decreased by another inch, the upper limit of dulness remaining during this time at the level of the left fourth rib in front. The improvement now continued without interruption, the patient putting on flesh and gaining strength, so that on Sept. 20th she was able to go out in a bath chair. The liver dulness also gradually diminished. On Sept. 28th the patient began taking petroleum emulsion and to have massage. The patient was weighed for the first time on Oct. 26th, having probably gained between two and three stones since May. Her weight was then seven and a half stones. She is now very nearly as well as ever, and weighs over nine and a half stones. Catamenia began again at the end of February, having ceased for a year. The liver dulness extends on the right side from the sixth rib to the costal margin in front and from the ninth rib to the costal margin behind. On the left side it extends from the fourth to the seventh rib in front and from the seventh rib to the costal margin behind.

Remarks.—This case is one of considerable interest and, it must be confessed, of some obscurity. I propose to consider the question of diagnosis as it presented itself at three different stages or periods of the case: (1) at the beginning of March, 1896; (2) at the beginning of May, 1896; and (3) at the present time. I. When seen in March the case appeared to be an ordinary one of atrophic cirrhosis with ascites. The usual etiology and the physical signs and symptoms all pointed to this conclusion. The impression given before tapping as to the small size of the liver was confirmed by the examination made immediately afterwards. Very marked improvement instantly followed the tapping, and there has been no re-accumulation of fluid since in the general peritoneal cavity. A certain amount of doubt must arise as to whether the ascites was due to the cirrhosis or to some other cause. Murchison states that when once ascites due to cirrhosis appears it persists and gradually increases. Hale White[1] has shown that when ascites in cirrhosis requires tapping the end is not far off, and this is borne out by Rolleston in his article in the *Midland Medical Review*, 1896. On the other hand, Cheadle[2] and Foxwell[3] maintain that the condition is curable, and give several cases in support of this view. Without affecting the correctness of the diagnosis there is the possibility that the ascites was not due to the cirrhosis found to exist in the liver, but independent of it. In this case it might be due either (1) to some pressure on the portal vein; or (2) to some local inflammation, causing chronic peritonitis with effusion. II. At the beginning of May, 1896, after about a month of apparent progress towards recovery, the clinical aspect of the case changed. The physical signs of enlargement of the left lobe of the liver appeared. The area of liver dulness increased very rapidly, its progress being observed from day to day, until in about four weeks there was extreme enlargement of the organ generally, its lower edge being distinctly palpable projecting well below the costal cartilages in the right mammary line and extending downwards and to the left in the left inguinal region. Above the thickened edge of the liver there were very distinct signs of fluctuation obtained in the epigastric and upper umbilical regions. The evidence given by palpation and percussion gave the impression of there being enlargement of the liver generally, with a very large cyst in the left lobe projecting upwards and downwards as well as forwards. Associated with the rapid enlargement of the liver there had been equally marked loss of flesh and strength. Pain was not a marked symptom and jaundice was absent. The lower edge of the liver and its surface were felt to be hard and smooth. At the time of our consultation on May 2nd there was no doubt in the minds of either Dr. Hayward or myself that we had to do with a case of rapid enlargement of the liver with the formation of a large cyst in the left lobe. The possible causes presenting themselves to our minds were: (*a*) abscess, (*b*) hydatid, and (*c*) malignant abscess (carcinoma or sarcoma). (*a*) As regards tropical abscess: (1) there was an absence of the usual etiology—viz., residence abroad or dysentery; (2) the characters of the fluid obtained by the exploring needle were not those of abscess; and (3) the general symptoms also combined to negative this hypothesis. Abscesses of the liver are sometimes caused by a gastric ulcer becoming adherent to the under surface of the liver and eroding that organ, or a foreign body perforating the gut and entering the liver. These theories were, however, equally untenable for the same reasons as tropical abscess, together with the entire absence of any previous history which could give support to such a supposition. (*b*) Hydatid was excluded by (1) the very rapid enlargement of the cyst under daily observation, and (2) by the characters of the fluid, this containing a large quantity of albumin (one-third) and chlorides, and being without any signs of hooklets or the characteristic membrane. Frerichs[5] records a case of sterile echinococcus presenting symptoms analogous to this case, but even here the characters of the fluid were quite different. (*c*) The previous suppositions having been negatived, there appeared only the remaining one of malignant disease. The considerations bearing on this possibility appeared to be: (1) although the patient looked very ill and greatly emaciated there was no cancerous cachexia; (2) the examination of the fluid gave negative results as far as the finding of any characteristic cellular elements was concerned; (3) nodulation of the liver surface and jaundice were absent; (4) still the positive facts of rapid enlargement of the liver substance associated with marked emaciation and prostration gave ground for strongly suspecting malignant disease; and (5) formation of cysts, sometimes of a large size, is not unknown in malignant disease of a sarcomatous nature,[6] and therefore sarcoma was considered more probable than carcinoma. This diagnosis at the time seemed so highly probable that an almost hopeless prognosis was given. III. The happy event of the patient's apparent recovery gives occasion for reconsidering the diagnosis in the light of the subsequent history and present condition of the patient, as well as that gained by further reference to medical literature,

to which may be added suggestions made by several distinguished physicians who have been good enough to take some interest in the case. 1. The retrocession of the liver tumour, together with the continuous gain in flesh and strength which have followed the last tapping of the cyst, seem to almost certainly negative the idea of malignant disease, although the natural cure of such disease is not wholly unknown.[7] 2. The same considerations which in the earlier stage of diagnosis sufficed to negative abscess and hydatid are still equally applicable. 3. Simple cysts of the liver are but rare, and three varieties of them are recognised by pathologists. (*a*) Small serous cysts, with clear watery contents, varying in size from a pea to a bean, are occasionally found in the liver, and are often accompanied by similar disease of the kidneys. They are multiple, and are supposed to originate in alteration of the hepatic cells. Their inner wall is covered with pavement epithelium, and presents membranous projections such as result when small cysts unite to form larger ones. No connexion can be made out between them and the bile-ducts.[9] (*b*) Kiener and Kilsch state that biliary polyadenomata found occasionally on section in cirrhotic livers may suppurate and form abscess cysts. These are, however, found in large cirrhotic livers.[9] (*c*) Occasionally a single cyst, containing inspissated mucus, has been found, and is generally considered to be due to partial obliteration of one of the bile-ducts, which has been subsequently shut off from the rest of the duct.[10] A specimen shown by Dr. Sharkey at the Pathological Society in 1882[11] presented a very unusually large cyst, but even this contained less than a pint of fluid. In this case there is unfortunately no record of the symptoms, as the patient was admitted to the hospital suffering from a fracture of the skull and died on the following day. 4. A case of pancreatic cyst reported from St. George's Hospital[12] presents some striking resemblances to my case, especially in the characters of the cyst fluid, of which a much more elaborate examination was made. As against the diagnosis of pancreatic cyst, however, the following considerations present themselves: (*a*) the cyst approached the surface of the abdomen above the edge of the liver and not below it; (*b*) the fluid was found by three observers to contain liver cells and what appeared to be bile-stained tissue; and (*c*) the liver, though considerably smaller than it was, is still enlarged. There remains the supposition that a cyst primarily of the pancreas may have secondarily involved the liver substance by continuity and that the liver cyst was therefore secondary. If such a condition has ever been observed post mortem, this would appear to be a possible diagnosis in this case. If, however, such a condition has not been observed one would think from theoretical considerations that a very rapidly growing cyst of the pancreas would be more likely to displace the liver upwards rather than to erode it, especially when one knows how extremely slowly an aneurysm erodes the neighbouring organs. 5. Another suggestion that has been made is that the case may have been one of accumulation of fluid in the lesser cavity of the peritoneum due to the blocking of the foramen of Winslow. Had we had to do with a case of cystic enlargement approaching the surface of the abdomen below the edge of the liver, and apparently in connexion with it, this, too, would have been a possible diagnosis; but the same facts which have been alluded to above as negativing pancreatic cyst are also of weight against this hypothesis, for the character of the fluid and the physical signs of the cyst seemed undoubtedly to point to its being in the liver substance. Jordan Lloyd has shown[13] by experimental injection of the lesser peritoneal cavity that the dulness reaches only just down below the umbilicus, whereas in this case it extended well down into the left iliac fossa. In addition to these objections there was the absence of the stomach note, which is usually present as a narrow resonant line separating the cyst from the liver. 6. These reasons, together with the absence of blood from the fluid and the absence of the history of any injury, serve also to exclude peritoneal sanguineous cysts like those described by Theodore Fisher.[14] 7. Knowsley Thornton[15] records a case in which he removed the spleen containing thirty ounces of blood-stained fluid. Such a cyst might possibly set up inflammation, and thus cause in the first instance peritoneal effusion. The fluid which I drew off contained no sign of blood on examination both microscopically or chemically, and the present symptoms of occasional appearance of white stools and continued hepatic enlargement point to liver rather than to spleen. 8. The same objections, together with the position of the cyst relative to the edge of the liver, would negative a hæmorrhagic adenoma of the left supra-renal body such as described by Létulle.[16] 9. An empyema perforating the diaphragm and setting up a subphrenic abscess would be contra-indicated by the total absence of symptoms pointing to such a condition and the characters of the fluid.

Assuming that error in observation and defective memory of impressions received can be eliminated, which, however, as we all too well know, are not wholly impossible, it would appear that the condition which I believe to exist in the final stage is the most probable one, viz., "a simple cyst of the liver, with a fibrous capsule and lined with granulation tissue," however rare and unusual such a condition may be. As to the cause and nature of the first origin of the cyst, some obscurity cannot but exist and the diagnosis must to a large extent remain doubtful, the art of diagnosis so largely consisting in recognising in a case before one a likeness to some case or cases previously seen, and failing this doubt must exist. Lastly, with regard to the question of treatment, that adopted in the first stage needs no comment. In the second stage the large and rapidly increasing size of the cyst so considerably pressing from below on the left pleural cavity seemed to demand some attempt to relieve the pressure. In the then apparent probability of the existence of malignant disease it was not considered advisable to use the aspirator for fear of internal hæmorrhage into the cyst cavity. The same consideration as well as the extremely weak condition of the patient contra-indicated at the time any attempt of a serious operation to explore and at the same time to deal radically with the cyst by drainage. The treatment adopted, when the patient's condition had somewhat improved, by slowly draining the cyst with a Southey's capillary cannula, whatever theoretical objections may be raised to it, in this case appears to have been attended with success. Under more radical treatment the patient might easily have done worse and could hardly have done better.

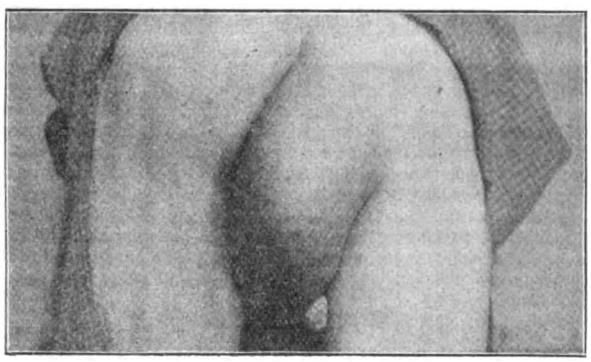
A CASE OF ISCHIO-RECTAL HERNIA DUE TO DISLOCATION OF A SUB-PERITONEAL FIBROMA.



BY J. LYNN THOMAS, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE CARDIFF INFIRMARY.

A MAN, aged sixty-two years, was sent to me by Mr. C. W. Hemming, who has very kindly supplied me with a full history of the case, and has also taken a keen interest in it for some years. About four years ago, whilst lifting a heavy weight, the patient felt a strain in the anal region, and the next day he noticed a rupture, which he pushed back, but it came down again immediately. The rupture increased in size until a year ago and since then has remained stationary. The swelling was increased by walking, was a source of trouble in defecating, compelled the patient to sit on the opposite tuber ischii, and for the last two years had incapacitated him for work on account of its size when he exerted himself. He had had no bladder trouble. The patient had always enjoyed good health, but was said to have dislocated his right hip ten years previously. The accompanying illustration shows the size and situation of the hernial protuberance and also the displacement of the right buttock-fold towards the left. The swelling extended anteriorly to the posterior extremity of the scrotum. The posterior portion of the tumour was reducible and contained intestine; the greater portion was irreducible, firm, elastic, slightly nodulated into three portions, and dull on percussion. With the finger in the rectum, the gurgling intestine could be felt descending into the hernia in immediate contact with the rectal wall on its right side, and occupying the ischio-rectal space from the

Digitized by Google

coccyx to the right tuber ischii, whilst nothing could be felt in front and behind its walls. On coughing impulse was conveyed to the whole tumour. Before operation I took the irreducible portion to be an epiplocele. The nodule near the lower border of the swelling was a molluscum fibrosum growing from the right thigh.

Operation.—On April 16th, 1897, with the patient in the lithotomy position, the skin thoroughly cleansed, and the rectum irrigated and plugged with an iodoform sponge, I made a long antero-posterior incision over the outer aspect of the swelling to avoid the gluteal fold. Several layers of thickened fascia with intervening cyst-spaces (bursal) were cut through, and many enlarged veins coursed over the surface of the tumour. A flattened muscular band about an inch and a half in width crossed over the tumour from the side of the rectum towards the inner aspect (rather deeply) of the tuber ischii, causing one of the boundaries of the nodulations previously described and firmly fixing the growth in its bed. There was a bursa between the muscle fibres, and it required some persuasion to convince one that it was not intestine before it was divided; as soon as this was done the tumour was easily shelled out without opening the peritoneum immediately under it. A large piece of redundant skin and fat was removed, the wound was closed, a drain was put in for forty-eight hours and an iodoform gauze dressing was applied and fixed by collodion after Professor Kocher's fashion, in his after-treatment of radical cure of hernia. The wound healed up quickly. The tumour weighed two and a quarter pounds; it cut like a moderately tough

The tumour as seen from behind.

fibroma. Microscopically it proved to be a fibroma undergoing myomatous degeneration. Before the patient returned home there was very little fulness in the ischio-rectal space; it bulged on coughing, and two fingers could be pushed into it, the coccyx, great sacro-sciatic ligament, and tuber ischii being thus easily felt. The patient sat and defecated with comfort.

Remarks.—Ischio-rectal herniæ are very rare in men, Macready, in his valuable "Treatise on Ruptures," having collected only six. This case I believe to be unique, inasmuch as the enterocele was primarily due to the dislocation of the sub-peritoneal fibroma through the ischio-rectal fossa. I have given the particulars fairly fully on account of the many points of interest in the case. The muscular band crossing the tumour I concluded to be a portion of the levator ani, because it was not directly attached to the tuber ischii and was too near the rectum to be the transversus perinæi. In Mr. William Anderson's notable contribution to the "Surgery of the Sub-peritoneal Tissue" it is stated that "the fibromata merge on the one hand into the lipomata; on the other into the myomata; and it is probable that many of the older reports of fibrous tumours really refer to myomata. Purely fibrous growths may, however, develop in the sub-peritoneal tissue"[1]; and in speaking of fibro-lipomata he states that "they sometimes comprise a considerable proportion of fibrous tissue, and, like the retro-peritoneal tumours, may undergo myxomatous degeneration." No trace of fat could be found in this tumour. This is the second case during the last few months that has impressed upon me the importance of Mr. Anderson's plea for treating the sub-peritoneal tissue as an anatomical entity liable to diseases of its own. The other case was one in which Dr. A. E. Taylor asked me to do a radical cure for a femoral hernia that was partly reducible, but returned immediately. I did so, fully agreeing that there was an epiplocele, but it turned out to be a serous cyst with a pedicle running up the femoral canal, and by pressing above Poupart's ligament two other cysts were delivered through the saphenous opening, and in dragging down the last one a cone of peritoneum was removed. I need hardly add that the "radical cure" was satisfactory.

My thanks are due to Dr. Wallace for his assistance at the operation, which was a very tedious one, and to Dr. F. P. S. Cresswell and Dr. Wood for sections of the tumour.

Cardiff.

NOTE ON A CASE OF GLIOMA OF THE RETINA.[1]

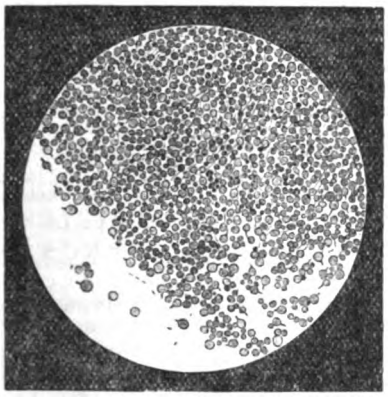
BY CHARLES BELL TAYLOR, M.D., F.R.C.S. EDIN.,
SURGEON TO THE EYE INFIRMARY, NOTTINGHAM.

THE patient to whose case I wish to call attention was a sturdy little fellow full of life and vigour, and, although very blind, was still able to stumble about, avoiding large objects. The parents were under the impression that the white shimmer perceptible within the child's pupils—for, strange to say, both eyes were alike affected—was caused by cataract; but a glance was sufficient to convince me that such was not the case, and I was able, by dilating the pupils and concentrating the rays of light, to demonstrate that not only was the lens in each eye perfectly transparent, but that its natural brilliance was greatly enhanced by a yellowish background of abnormal growth with bossy surface, traversed by tortuous blood-vessels.

The growth could not be a simple non-malignant tumour, for such a thing was never heard of in this situation. It could not be sarcoma, because sarcoma is a disease of more advanced life, and is never bilateral. It could not arise from

FIG. 1.

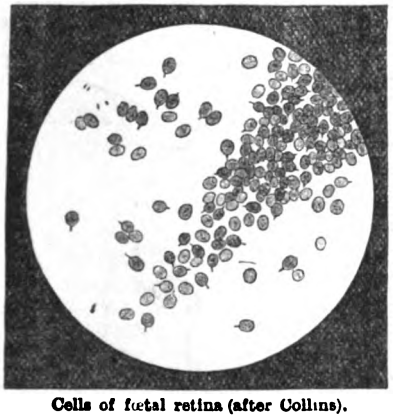
View of patient previously to operation.



suppurative choroiditis or deposit of purulent matter in the vitreous chamber (pseudo-glioma as it is called), because such a condition is always preceded by accident or serious illness, and is accompanied by iritic changes and softening of the globe. What, then, was it? There can be only one answer to that question. It was medullary cancer or glioma of the retina, a disease which is certain to end fatally if untreated, which is apt to recur in the orbit after excision of the eyeball, and in a large proportion of cases to reappear in the sound eye, even years after the ablation of its fellow. Above is an illustration (see Fig. 1) of a patient under my care whose right

[1] This note was read, and the patient was exhibited, at the meeting of the Nottingham Medico-Chirurgical Society on Feb. 3rd, 1897.

Digitized by Google



eye I excised on account of glioma with perfect success in her third year, and who succumbed to a recurrence of the disease in the left eye (which was not excised) in her sixth year. This is a black record for glioma, but we must not allow it to blind us to the facts that the subjects of glioma are for the most part children who show no sign of constitutional cachexia; that the disease never appears later in distant organs, such as the liver, for instance, by metastasis, as sarcoma does; that it never recurs either *in loco* or in the sound eye after three years of post-operative immunity; that it has never been seen in children over eleven years of age; and that its histological elements, simple round nucleated cells (never spindle cells), are not to be distinguished, as Mr. Treacher Collins has pointed out, from the normal cells of the

FIG. 2.

Glioma cells.

FIG. 3.

Cells of fœtal retina (after Collins).

fœtal retina. In short, the disease, although so serious in character is, in my opinion, in the first instance a purely local affection, which spreads only by continuity of tissue,[2] and I believe as a result of great experience that if the eye is excised while the growth is confined to the retina there will be no recurrence in the optic nerve or orbit of the affected eye, and that if the same operation is performed in good time upon the second eye should it become affected a like result may be attained.

It is clear, therefore, that the only course to pursue in the present case is to recommend extirpation of both eyes—a grim alternative, which the parents naturally regard with dismay. Nevertheless, it is our only resource and the least of evils, for if nothing is done, humanly speaking, the disease will spread backwards and forwards, the eyeballs will slowly distend until they give way and protrude from the orbits, and bleeding masses of fungus, offensive and ulcerated, will appear upon the surface, and will prove fatal to the patient and heart-rending to those who, compelled to watch over their child's slow dissolution, will reproach themselves that they refused the only chance of cure, when cure alone was possible.

Nottingham.

[2] In cases where the disease has re-appeared in the sound eye the optic nerve has been found to be quite healthy, thus proving that the growth was quite independent and had not spread, as some have supposed, through the optic tract from one eye to the other.

A NOTE ON RUPTURE OF INTRA-THORACIC AORTIC ANEURYSMS BASED UPON AN ANALYSIS OF THIRTY-TWO CASES.

BY T. N. KELYNACK, M.D. VICT., M.R.C.P. LOND.,
PATHOLOGIST TO THE MANCHESTER ROYAL INFIRMARY; DEMONSTRATOR AND ASSISTANT LECTURER IN PATHOLOGY TO THE OWENS COLLEGE.

THE occurrence of rupture of an intra-thoracic aortic aneurysm is an event which not only raises questions of clinical importance, but points of much pathological and medico-legal interest. I therefore venture to think that some brief reference to cases which have been met with in the Pathological Department of the Manchester Royal Infirmary may not be without some value.[1]

Number and proportion of cases.—Among the last 4593 cases submitted to pathological examination rupture of a thoracic aneurysm has been noted in 32 cases. This gives a percentage in all "general" cases of 0·69.

Sex.—Of the 32 cases, 30 were men and only 2 women—that is, a percentage of 93·75 males and 6·25 females.

Age.—The exact age was obtained in 30 of the cases; the others were middle-aged males. The average age was forty years. The males averaged 40·4 years. The females averaged thirty-four years. The youngest subject was aged twenty years and the oldest was aged sixty-five years.

Seat of aneurysm.—In many instances the greater part of the arch was involved. Grouped, however, according to the chief area of affection they may be arranged as follows: Ascending portion of arch, 12; transverse portion of arch, 11; descending portion of arch, 4; and descending thoracic aorta, 5.

Point of rupture.—This can be best indicated in tabular form:—

Part ruptured into.	No. of cases.	Percentage.
Pericardium	13	40·62
Pleura (left)	7*	21·87
Œsophagus	3	9·37
Externally	3	9·37
Trachea	2	6·25
Pleura (right)	1	3·12
Lung (left)	1	3·12
Bronchus (right)	1	3·12
Superior vena cava	1	3·12

* One of these was a case of dissecting aneurysm.

Nature of death.—Of the thirty-two cases, six were observed in medico-legal investigations, the subjects being brought dead to the hospital, having been found dead or suddenly seized in the street or elsewhere. In one instance a man while riding in a cart suddenly fell out of the vehicle and was picked up dead. In nearly all the cases where rupture occurred while in hospital or where a clear history could be obtained death was sudden, in many instances being practically instantaneous. In one case where rupture occurred into the œsophagus death took place in five minutes. In another, where the aneurysm burst into the pericardium, the patient felt faint and was dead in three minutes. In one subject, where the pericardium was found filled with blood, and where there was commencing erosion into the trachea, with also extension into the left lung, a small quantity of frothy blood was brought up for some hours before death, which was sudden. In a case where there was general aneurysmal dilatation of the arch of the aorta rupture took place into the pericardium through a vertical slit two and a third inches in length. The patient was brought to the hospital in what appeared to be a syncopal attack and died suddenly four hours later. In one case where death occurred suddenly blood-clot weighing eighty-five ounces was found in the left pleural cavity.

Manchester.

[1] These cases are strictly limited to aneurysm of the thoracic aorta. Aneurysms of the innominate and subclavian are not included. The question of rupture of cerebral, abdominal, and other aneurysms I hope to be able to refer to in a subsequent note.

TWO CASES OF "ELECTRIC-LIGHT BLINDNESS."

BY ROBERT HILL, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON, ROYAL NAVY (H.M.S. "VICTORY").

I VENTURE to forward for publication in THE LANCET the following cases that have come under my notice lately, hoping that they may be of interest to its readers, and more especially to those engaged in ophthalmic work.

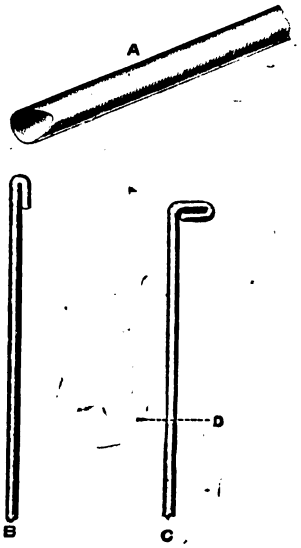
CASE 1.—About 1 A.M. on June 1st, 1897, I was called hurriedly to see a man who was said to be suffering great pain in his eyes. The man, a stoker, twenty years of age, I found walking round the sick bay of this ship in an agony of pain, with his hands up to his eyes from which the tears were literally pouring. The lids were kept firmly closed, and all my efforts to see the eyes proved futile until I had dropped in cocaine, which acted like a charm. Five minutes later he could distinguish the number of persons in the room, but not the number of fingers held up. The pupils were moderately dilated (probably due to the cocaine); the palpebral conjunctiva was deeply congested, with but slight reddening of the bulbar conjunctiva; the cornea was clear. I imagined some irritant had been applied, but he denied this, nor could I find any trace of any substance such as pepper likely to cause the condition. Cold applications were used and the patient soon fell asleep. At 8 A.M. his vision was normal, but the conjunctiva was injected, and he complained of a sticky sensation in his eyes. He then gave me the following history. When at work in H.M.S. *Mars* on the afternoon of May 31st he had stopped for about three minutes to look at the electric drill which was being used to bore holes in a steel plate, standing at a distance of from ten to twelve yards; on resuming his own work everything appeared to him of a deep gold colour, but he had no pain or lacrymation. He turned into his hammock at 9 P.M., and woke up in great pain at 12 30

CASE 2.—At 9 A.M. on June 1st a stoker, aged twenty-eight years, who had been sleeping on shore, came to the sick bay complaining of his eyes. He stated that he had been working in H.M.S. *Mars* on the previous afternoon, and, like the patient in Case 1, had stopped to see the electric drill working, and had noticed during the remainder of the day that everything appeared of a deep gold colour. About 4 A.M. he had jumped out of bed in great pain, and this had lasted about an hour and a half. The condition of the eyes was very similar to that described in Case 1—injection of the conjunctiva being the only abnormal condition. Vision was normal.

Ever since the electric light has been in use workers at this trade have been subject to attacks of blindness, and cases have been recorded in which erosion of the cornea has followed the inflammation induced. Dark glasses are now always used by men so employed. The electric drill acts by fusing a hole through the steel, and probably the intensity of the light is greatly increased by the rays of light thrown off by the molten metal. The fact that the work is carried on chiefly in the daylight hides to a casual passer-by the extreme brilliancy of the light, and it is not until the patient experiences abnormal colour sensations that he is aware of anything extraordinary. When first this drill was used in Chatham Dockyard Surgeon P. N. Randall had a few similar cases among the dockyard hands, but as they slept on shore he had no opportunity of observing the acuteness of the pain.

The pathology of this condition has been stated to be similar to that of snow-blindness or desert blindness, and to depend on irritation of the branches of the ophthalmic division of the fifth nerve. In the cases above recorded the irritation would appear to have gone on to absolute paralysis and the pain to have been due to the acute congestion attending the nerves in their action of regaining their normal function. A somewhat analogous train of circumstances is found in the paralysis of the sensory nerves of other parts of the body when exposed to extreme cold, such as the ether spray or frost-bite, and the pain in these cases is often very great when the congestion attending the "coming to" of the part takes place. The short period during which the severe pain lasted is also in favour of this analogy. The close sympathy that exists between the second nerve and the branches of the ophthalmic division of the fifth nerve is shown in many common and well-known reflexes, such as lacrymation and sneezing on sudden exposure of the eye to a bright light, or, conversely, the dread of light that is caused by any injury to the cornea. In the class of cases described we have a marked instance of the first class of reflex. A temporary paralysis of some of the optic nerve terminals is induced by the exposure to the intense light and heat of the electric drill as shown by the subjective colour sensations experienced. The corneal terminals reflexly share in the paralysis; lacrymation and photophobia are absent because the nerve terminals are paralysed and not merely irritated at the time. After the lapse of a few hours a reaction with temporary congestion is set up as manifested by the acute pain and lacrymation, and probably some mistiness of vision. The longer the exposure to the bright light the profounder the paralysis and the more intense and lasting the reactionary symptoms. These cases are, in fact, analogous to snow-blindness, and, as in them, the pernicious effects of the electric light are probably due to the ultra violet rays of the spectrum.

Portsmouth.



THE TREATMENT OF LACRYMAL OBSTRUCTION BY STYLES.

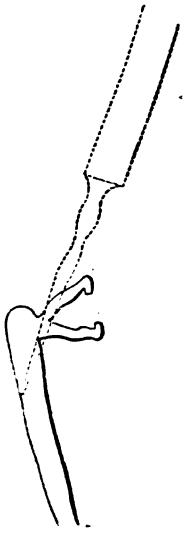
BY R. SHALDERS MILLER, F.R.C.S. ENG.

THIS little section of surgical therapeusis has probably been less successful than the operative treatment of other disorders of the eye and its subsidiary apparatus.

Since 1877, when I first became a clinical assistant at the Royal London Ophthalmic Hospital, Moorfields, it has been my habit to treat all organic strictures of the lacrymal duct—that is, all parts of the outfall from the lower punctum lacrymale to the exit in the inferior turbinate sinus of the nose—by styles, in most cases permanently retained. Except for temporary wear they should be made of pure platinum wire, about 25 gauge, and I always make them myself for each individual case. The shape, direction, and length of the nasal duct being variable this special adaptation is the key to success in the use of styles, which consist of a vertical stem with a short arm bent at or about a right angle to the stem and usually this arm is made double by recurving the wire back to the stem, so that the arm consists of two thicknesses of wire, parallel and quite close together, the recurved part being vertically beneath the other, or upper, part. In this way the slit in the edge of the lid is just filled up, but no

FIG. 1.

A shows the wire (magnified for clearness) with an oblique notch filed in the end to fit into the angle between the arm and the stem. B indicates the first bending of the wire, the notch facing the stem. C indicates the final bending, and D the place where the stem is cut off.



Digitized by Google

metal is visible unless the lid be everted. Sometimes the furrow produced by slitting up the canaliculus is very shallow; then the arm of the style is single. The length of the arm should be such that it easily fills the slit-up canaliculus; it should not be tight. The stem should always be long enough to project through the lower opening of the duct in the inferior nasal sinus.

The practical effect of a style in maintaining the patency of the lacrymal exit depends upon the lateral movements of the lower lid, imparted by those long, straight muscular fibres which take origin at the tendo palpebrarum and run horizontally outwards to the surface of the malar bone and are anatomically quite separable from the oval bundles of the orbicularis proper. The tubular styles of the instrument makers are worse than useless; they soon become choked with mucus and dust. Also in the case of the grooved styles the necessarily thin edges of the groove cause irritation and the production of a granulation which stops the way. The stem should not be straight, except in the case of a very short duct, but somewhat concave outwards. The lower opening of the duct may be obstructed by a lower turbinate excessively curved towards the outer nasal wall, but even this is scarcely an excuse for turbinotomy.

I have found no difficulty in pushing a probe through the turbinate bone, and the style, made long, follows suit. Some of my patients have worn a platinum style for eight or more years without its ever having been removed from the moment of its first introduction. In every case of lacrymal abscess a style ought to be used—for a time at least—and in most instances is needed permanently; but a temporary one must be first introduced, of a form modified according to the amount of swelling in the part. Such style may be of lead or silver, and several different forms and sizes are sometimes desirable in succession to suit the changing size and shape of the lid and canthus. I have once found it necessary to make an eyed probe of lead wire, pass it through the duct and anterior naris, and, by means of a thread attached, pull a fine drainage tube through and thus restore a lacrymal passage which had been obliterated by an encysted abscess for sixteen years. A platinum style was afterwards worn with a perfect result. The wire for making these styles, together with more detailed information as to their manufacture, may be obtained of Messrs Curry and Paxton, Great Portland-street, W., who have lent the blocks for the accompanying illustrations. They will also make platinum styles from patterns of lead wire supplied to them by those who prefer not to undertake the construction of permanent instruments.

FIG. 2.

In the little operation preliminary to the insertion of a style the chief obstacle likely to be met with is the spur or projecting angle (see Fig. 2) formed by the lower boundary of the conjoint opening of the canaliculi and the adjacent part of the lacrymal sac—that is to say, the outer wall of the sac below the opening of the canaliculi. The lower canaliculus is slit up with either a Stilling's or a Weber's knife. The latter sometimes finds its way more easily, but as a rule I use a Stilling's knife throughout. I have here drawn (*vide* dotted lines in figure) an exact representation of my favourite knife, which has been reduced by several occasions of sharpening to a somewhat more slender form than the original. This traverses the canaliculus easily, and yet is strong enough at the base to be safe from breakage. A Weber's knife should never be passed down the duct; the blade is apt to stay there, of which mishap several examples have come to my knowledge. The canaliculus being slit up, the Stilling's knife is passed down the duct in the ordinary way, and in withdrawing is rotated till the edge of the blade looks directly outwards and the handle is inclined towards the external angular process of the orbit so as to bring the edge of the knife firmly against the above-mentioned spur (see Fig. 2), which is divided in drawing out the knife. A Couper's probe, about size 5 or 6, is then passed and allowed to stand for a minute or two, and the length of the part introduced is noted when the probe is withdrawn. The stem of the style should generally be about an eighth of an inch shorter than such measurement. It might be supposed that the division of the spur would cause hæmorrhage into the sub-palpebral tissues. This rarely happens, and when it does nothing more than a "black eye" ensues, and this can be reduced to almost nothing by tying up the eye with a pad kept wet with hazeline for a few hours. Styles are, of course, not needed in cases of temporary lacrymal obstruction, such as acute catarrh of the sac and comparatively recent mucocele, or in some obstructive conditions resulting from nasal disease. Irrigation with mild antiseptic fluids should have a fair trial before adopting any operative measure, except in lacrymal abscess. The repeated passing of probes is highly objectionable, and styles made of improper materials are perhaps worse.

The movement of the tears towards the inferior turbinate sinus is initiated by the capillary effect of the canaliculi, and by the action of the tensor tarsi muscle, and is continued by the ciliated epithelium which lines the sac and ductus ad nasum. But capillarity is not an attribute peculiar to cylindrical tubes; it occurs equally well between plane surfaces, as every worker with the microscope is aware, and a properly slit canaliculus is not a yawning chasm but a neat cleft with flat parallel surfaces in contact with each other and when a well-fitting style is *in situ* capillary attraction goes on readily between the style and the inner surfaces of the furrow containing it. Capillarity is a physical property which is more or less manifest whenever a liquid is in contact with a solid. An occasional cause of lacrymation, partly due to irritation and partly to obstruction, is the presence in either the upper or lower canaliculus of an eye-lash which leaves a short piece of one end projecting from the punctum. This end scratches the eye, and I have known the resulting irritation mistaken for "hay-fever." This impaction of an eye-lash has come under my observation twice in the lower canaliculus and once in the upper.

Windsor.

NELSON AS A PATIENT.

BY EDMUND OWEN, F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL.

A FEW months ago Mr. C. Fraser-Mackintosh, of Inverness, showed me an autograph letter of Nelson's, which, to the best of his belief, had never been published. As I deemed it of considerable interest from a surgical point of view I asked for the loan of it so that a *facsimile* might be made for THE LANCET. This he kindly granted.

Exactly 100 years ago to-day—namely, on the night of July 24th, 1797—Nelson with about 900 men left the frigates which were anchored off Teneriffe and proceeded in open boats to the desperate attack on Santa Cruz with what Captain Mahan calls "superb courage."[1] "In the act of stepping out of the boat," says Southey, "Nelson received a shot through the right elbow and fell." He might have bled to death. But even at that time the principles of First-Aid, which the benevolent Society of St. John of Jerusalem have in recent years done so much to popularise, were not unknown, for we are told that one of Nelson's officers bound some silk handkerchiefs tightly above the lacerated vessels and so arrested a profuse hæmorrhage, whilst "one of his bargemen tore his shirt into shreds and made a sling with them for the broken limb. ..... Had it not been for this Nelson must have perished." As soon as he was once again aboard he told the surgeon to get his instruments ready, for he knew that he must lose his arm, and that the sooner it was off the better. Unfortunately, after the amputation the nerve (the median, I suppose) was included in the silk ligature which secured the main vessel. This was truly a calamity; it caused the hero intense and prolonged suffering. In those days the ligature-threads were not cut short as now, but were brought out at a corner of the wound to provide a needful drain for the customary septic discharge; and some of us can recall instances in which a premature attempt to get away a ligature was followed by alarming secondary

[1] The Life of Nelson. London: Sampson Low and C°. 1897.

Digitized by Google

hæmorrhage. The presence of the ligature in the case of Nelson must have given neuralgic pains which were referred to the hand and fingers of the amputated limb, and, what to him was equally serious, the fact of the wound not being healed kept him fretting on shore when his sole desire was to be on active service.
